Best Practices in Crisis Intervention

Scott Poland

INTRODUCTION

Crisis intervention skills for school psychologists are becoming indispensable as the numbers of crises in our schools spiral upward. At present all schools are at risk for crises — even "successful" schools in prominent neighborhoods (Jay, 1989).

Although few of us feel completely prepared to face and manage shootings, kidnappings, emotionally out-of-control staff members, or assaults of teachers, the simple reality is that most of us will. Government figures for 1985 documented 450,000 violent crimes in our nation's schools and colleges. Assaults accounted for most of the incidents, followed by robbery and rape (Mayfield, 1986). Keen (1989) noted that three million children are attacked at school each year and that weapons were used in 70,000 assaults. A recent 50% increase has been cited in the number of attacks on teachers from 1973 to 1985, and youth homicide has doubled in the last 20 years (McEvoy, 1988). Memmot and Stone (1989) report that one child is killed every day in accidental shootings and 10 more are injured.

Several years ago our department of psychological services received a phone call from a superintendent requesting that psychologists be sent to the site of an in-school shooting. Precisely what had happened, who was in charge, or how exactly we might benefit the situation was completely undetermined. Nothing could have prepared us for what we found: Television news teams roamed the halls, large numbers of frightened students were unaccounted for, telephone lines were clogged with frantic calls from parents, teachers were rattled from the near hysteria, and administrators felt ill equipped to manage the barrage of problems that fell upon them in the course of a fleeting moment. It was generally felt that a psychologist ought to know what to do with an incident that carries with it such emotionality. Those of us who approached the scene, however, felt the same sense of helplessness, anxiety, and confusion.

Since administrators frequently see school psychologists as the "experts" in this area and since we may be the only school personnel trained in the management of strong emotions and preventive program planning, it is logical that the crisis intervention responsibility fall squarely on us. Our profession, however, has been slow to prepare us for such a role or to be proactive in establishing and organizing crisis intervention activities in the schools (Smead, 1985).

For example, Lazarus and Phelps (1993) noted at a recent meeting of the Trainers of School Psychologists that trainers had not received systematic coursework in crisis intervention nor been trained in basic skills such as debriefing or psychological first aid. Therefore, in recent years, much of the training for the profession has become the purview of practitioners who learn their crisis intervention skills in the field (e.g., Franzen, 1993; Kamins, 1993; Pando, Laska, & Grant, 1993; Poland, 1993; Reynolds, 1993; Young, 1993).

Perhaps as school psychologists expand their attention to providing school psychology services to all children and not just youngsters in exceptional student education, the focus may shift. In a recent position statement put forth by the National Association of School Psychologists (1993) entitled *On Advocacy for Effective School Psychological Services for All Children*, NASP convincingly argues for comprehensive psychological services to include "developing crisis intervention plans and providing services in reaction to crises (such as suicide attempts, school and neighborhood violence, natural disasters)."

Lazarus (in press-a) makes the point that by emphasizing crisis intervention activities, school psychologists can attest that they are essential services rather than support services.

At a recent workshop, Kamins (1993) explained how his district added school psychology positions at a time of financial cutbacks by emphasizing to the school board and the superintendent all the crisis activities his staff had engaged in on a weekly basis. They did this by sending a memo to the superintendent of schools every time they intervened to prevent a crisis from occurring or escalating and explained how they had responded during and in the aftermath of a traumatic event. When lives were saved as a result of their intervention, this became their most potent rationale for the creation of new positions.

Though Smead (1985) has correctly criticized our profession for being slow to establish and organize crisis intervention services, it appears that in the nineties workshops (e.g., Franzen, 1993; Kamins, 1993; Pando et al., 1993; Poland, 1993; Reynolds, 1993; Young, 1993) and symposiums (e.g., Busher, 1990; Dillard, 1990; Lipton, 1990; Poland, 1990), and texts (e.g., Pitcher & Poland, 1992; Slaikeu, 1990) have begun to educate practitioners on how to deliver crisis intervention services and develop crisis response teams (Alderman, 1989; Armstrong, 1989; Lazarus & Howard, 1993; Pitcher & Poland, 1992). Recently, NASP (1991) published a compendium entitled *Resources in Crisis Intervention: School, Family, and Community Applications*. Moreover, the number of NASP presentations at annual conventions that were directly related to crisis intervention has increased from 3 in 1983 to 17 in 1993. Therefore, it can be seen that the profession is moving forward in taking on this critical role. The title of a recent article, "Crisis Response Teams a Must for All School Districts" (Neuhaus, 1990), may become the norm at the beginning of the twenty-first century and exemplifies the primary assumption in this chapter.

This chapter will outline a practical model for crisis intervention in the schools that will enable school systems to organize and respond effectively in the face of a crisis. The role of the school psychologist ranges from that of manager to trainer to program planner. The overall model first establishes competent reaction to crises, then presses on to establish competent prevention of crises. It is our intent to pass along the information we have accumulated in nearly a decade of research and management of school crises (Pitcher & Poland, 1992).

BASIC CONSIDERATIONS

Probably the most pronounced aspect of a crisis in the schools is the intense emotional upset or "disequilibrium" experienced by the system. Much as in personal crises, staff members experience feelings of helplessness, denial, inadequacy, and confusion. If the crisis is not resolved, depression or burnout, physical symptoms, and disorganization of functional working relationships occur. It is for this reason that school psychologists are frequently seen as the most appropriate personnel to intervene and support staff in crises.

In inexperienced or unprepared districts, however, psychologists are typically summoned at the least advantageous moment. Traditionally, crises have been regarded as unfolding in four stages: First, there is an initial rise in tension due to the crisis event. Second, in the face of the continued impact of the stressing event, there is a lack of success in the usual problem-solving techniques. During the third stage other problem-solving resources are mobilized, and, following failure of these, tension mounts to the breaking point during the fourth and final phase of severe emotional disorganization (Caplan, 1964). All too often school psychologists are called during the last portion of the third or fourth phase. It is necessary, then, that we develop the arsenal of skills required to have a positive impact on the organization at that time.

However, there is a second and very significant aspect of crisis in the schools that we must prepare ourselves and our profession to embrace. During and just subsequent to crisis there is a reduced defensiveness or increased openness on the part of the system, again paralleling personal crisis. Crisis has been frequently recognized as a time of potential danger as well as potential opportunity (Wilhelm, 1967; Lidell & Scott, 1968, Slaikeu, 1984). If our profession is able to manage the danger — that is, manage the immediate crisis and quickly return the system to normal functioning — then there exists a tremendous opportunity to stimulate long-term systemic change. Once seen as effective and credible, the psychologist has infinitely more opportunity to move the system in the direction of prevention. Thus, the general intent of our approach is actually twofold:

1. To establish crisis management procedures that support effective coping/management behavior during extreme emotional states (which will return the system to normal functioning as quickly as possible).

2. To introduce crisis prevention activities that will reduce the probability of the reoccurrence of crisis.

As in public health, our concept of prevention can take three forms: primary prevention, secondary prevention, and tertiary prevention (Bloom, 1977; Caplan, 1964). Primary prevention includes activities that prevent crises from occurring altogether, secondary prevention includes activities that arrest potential crises from escalating, and tertiary prevention aims to repair damage from the occurrence of a crisis (i.e., crisis management). By way of illustration, then, primary prevention might be educating elementary school teachers regarding custody laws and establishing school policies and procedures to regulate authorized removal of a child from the school. Secondary prevention might involve effective implementation of such safeguards, while tertiary prevention would involve competent management of a crisis in which a child has been removed from school by an unauthorized person.

School psychologists who have been trained in organizational and community intervention will quickly recognize primary and secondary prevention as the mainstay of most systems-level interventions (Danish & D'Augelli, 1980; Rappaport, 1977; Reiff, 1975). However, school administrators, in the most-frequent-case scenario, are infinitely more amenable to primary or secondary activities once they have found themselves face to face with the tertiary prevention problems of managing a crisis. In reality, therefore, school psychologists are frequently faced with the somewhat illogical approach of beginning to intervene at the tertiary level of crisis management, and only later focusing on primary and secondary activities. Enter the tremendous opportunity for school psychologists in crisis intervention.

Administrative personnel who have managed an intense crisis are far more motivated to avoid having to do so again. Frequently this phenomenon occurs at the highest levels of administration and the school board. These individuals are scrutinized by the entire community for making the "right" decisions under pressure. The question rises from parents, children, the media, and faculty: What's being done? Those districts who can answer this question most convincingly and reassuringly are those who have planned activities and procedures along all three avenues of prevention, as stressed by the present model.

For example, in a recent series in the *School Administrator*, a number of administrative personnel, including superintendents, associate superintendents, and principals, emphasized the importance of crisis intervention in the schools (Barish, 1991; Caylor, 1991; Colley, 1991; Coonan, 1991; Dunne-Maxim & Underwood, 1991; Excel, 1991). Caylor, superintendent of Huntsville, Alabama, city schools described how her school district developed an emergency response plan several years *after* a middle school was destroyed by an arsonist (Caylor, 1991). A young boy had set a stage curtain on fire that engulfed the school in flames. She commented, "We learned about dealing with a crisis the hard way" (p. 17). Since then, plans have been developed to address many situations: fire; bomb threat; explosion; ice/snowstorm; severe weather; hazardous materials; building intruder; off-campus/emergency bus wreck; and injuries to students, nonstudents, and employees; as well as student evacuation from schoolgrounds. The major point she makes is that the importance of developing a crisis plan cannot be overstated.

Excel (1991), the principal of the Cokeville Elementary School in Cokeville, Wyoming, described how his school was taken hostage by a couple with guns and a homemade bomb. They herded 150 people into a first-grade classroom and held the group hostage. Excel mediated the hostage takers' demands with the police. However, the bomb accidentally exploded, blowing out the ceiling and setting the room and all the occupants on fire. Fortunately, no children or staff members died, though many were badly burned, and 86 students and teachers were sent to area hospitals. After this trauma, the area psychologists taught parents and teachers how to cope and in turn how to help the students deal with the aftermath of this tragedy. It appears that administrators are not only beginning to appreciate the importance of planning for crisis, but also the crucial role that school psychologists can take in facilitating the coping process. The most innovative districts are now beginning to recognize the value not only of tertiary prevention, but primary and secondary prevention as well.

BEST PRACTICES IN DEVELOPING A DISTRICT PROGRAM FOR CRISIS INTERVENTION

Nelson and Slaikeu (1984) pointed out that crisis intervention needs to be included in the job descriptions of school personnel such as administrators, counselors, and school psychologists. Guetzloe (1988) emphasized that educational associations are recognizing that more needs to be done in preparing schools to deal with a crisis. Guetzloe pointed out that California in 1982 mandated that schools be safe and stressed the following points:

1. Teachers and administrators should be trained in crime prevention and safety procedures.

2. School security engineers should approve of school construction and schools have a responsibility to keep students safe.

Historically, attempts to prevent a crisis from occurring at school have concentrated on evacuation procedures such as fire and natural disaster drills. The incidence of violence in our schools and society indicates that we have to prepare for violent behavior. As one teacher put it, "We have to be prepared for a violent intrusion from an outsider or violent behavior on the part of a member of our school."

An examination of a number of school district procedures on crisis intervention is enlightening. Most procedures address chain-of-command issues such as when to call the superintendent or security and whether to evacuate the building in the event of a bomb threat. These organizational issues are certainly important but a crisis team that can provide a range of services is needed.

There is little information about exactly how crisis teams are organized. Ruof and Harris (1988) described three options in setting up a crisis team:

1. An inside model, which includes only staff from one building on the crisis team.

2. An outside team, composed of community mental health professionals or itinerant school personnel such as school psychologists and special education personnel.

3. A combined model that utilizes building personnel and professionals who do not regularly work in the building.

Ruof and Harris point out that there are many advantages to the inside team format because students know the team members, and they are more immediately available. A disadvantage may be that a building may not have the necessary personnel or the personnel may not have crisis intervention skills. The outside model utilizes more trained personnel, but they do not know the students and must be called to the building. One outside crisis team reported to us that they were ready to assist in the aftermath of a student's death but that the principal did not call on them. Pelej and Scholzen (1987) and Schulman (1986) have cautioned against the school system's always calling in outside experts when a crisis occurs. Ruof and Harris cited two additional problems with this approach. There may not be enough itinerant school personnel to call on and the outside professionals may be too costly. Comstock (1985) stressed that outside mental health professionals are willing to assist at little or no cost if the school system will involve them in a meaningful way and listen to their recommendations. The combined model is recommended by Ruof and Harris because it utilizes personnel in the building who know the students as well as the expertise of itinerant school personnel or community mental health personnel.

Selecting crisis team members is very important. Ruof and Harris (1988) recommend that membership on the crisis team be voluntary. Team members should not only be willing but should have attributes and skills that will enable them to perform well. The question of how many school personnel should be on a crisis team was discussed by Ruof and Harris, who recommended a minimum of two and preferable one team member per 100 children. We recommend that teams be composed of four to eight. Fewer than four team members may not provide enough team members to manage a crisis and more than eight team members results in confusion. A team approach is needed because no single person can do everything; principals have commented that they could not be in the four or five places they needed to be at the same time during a crisis.

Theoretical Model

Crisis team members need to be familiar with Caplan's (1964) model. Most people think of crisis intervention only as what is done in the immediate aftermath of a crisis, but the most important issue is what can be done to prevent a crisis from happening. One principal who experienced a shooting at school feels very strongly that students must not keep a secret about life-threatening behavior. Many efforts have been directed towards improving and maintaining close communication between faculty and students. Too often students know about potential crisis events but keep the information to themselves. It is not possible to specify all the *primary prevention* activities that a crisis team could be involved in. Examples are high schools that decide to do something about drunk driving by establishing a safe ride program and to work to prevent teen suicide by establishing a school crisis helpline. A local teacher rehearsed a "secret signal" of danger with her class; her students followed her cue and violence was averted when a gunman entered her class. The following are the types of questions that crisis teams need to think about to prevent a crisis.

1. What is worrisome about the school or the neighborhood?

2. Is there a potentially violent student or parent?

3. How could we notify students to stay away from windows or to evacuate the playground or the school quickly?

4. If we evacuate the school, where do we go?

5. What has worked or not worked in handling a crisis situation in the past?

6. Is all playground equipment safe?

7. Do school personnel know CPR and first aid? Who will summon medical assistance? What if the nurse is not available?

8. How can a teacher summon help from the office?

9. Does the school offer a gun safety program?

10. Is the school system prepared to deal with the media?

11. Have school staff been provided with information on how to deal with a violent individual?

12. What communication systems are available to contact police and to inform the superintendent of schools?

Dillard (1989) made these additional recommendations for primary prevention.

1. Know how to call on mental health resources in your community.

2. Establish close cooperative relations between the school system and police and fire departments.

3. Be prepared to provide continuing assistance to students, their parents and school staff after a crisis. Group meetings held at school can convey factual information and dispel rumors.

Many issues concerning safety also need to be addressed in the curriculum. One of the most important involves educating students about gun safety. Ten children each day under the age of 18 are killed in handgun suicides, homicides or accidents (Memmot & Stone, 1989). One school system that is educating its students about gun safety is Dade County in Florida. Doup (1989) reports that the program begins in the first grade and is modeled after drug prevention programs.

The *secondary level* of intervention in Caplan's (1964) model emphasizes responding quickly to minimize the chance of long-lasting effects to a crisis. School buildings may want to form medical emergency teams and rehearse their response to various situations. Control of students is also very important. Plans need to be developed to direct students to classrooms or out of the building without mass confusion. One high school crisis team has made evacuation arrangement with local churches near the high school campus. The team also has ready a "crisis box" with materials that would be needed in the event that the school needs to be evacuated. The school faculty must also be told promptly when a crisis occurs. Thought needs to be given to how to accomplish that. The faculty needs to process the crisis event and their feelings about it as soon as students have gone home. This meeting to process the event can also be used to plan for the next school day.

Contacting law enforcement personnel is also part of secondary intervention. What law enforcement personnel will be called and what to expect when they arrive are important questions to be addressed. Contact with parents is also very important. The parents of injured and upset children need to be contacted. Parents might simply appear at the school and might be upset and make demands upon the school or they might come to help out. One crisis team elected to involve parents by contacting parents who lived near the school and were home during the day and making them a part of their crisis team. Communication to parents after a crisis also is very important. It is important to clarify how this communication will take place and who will do it.

The emotional effects of a crisis must also be dealt with immediately in order to minimize long-lasting debilitating effects. This point is well illustrated by Sandall (1986), who not only discussed immediate steps taken in the aftermath of a school bombing in Cokeville, Wyoming, but contrasted actions taken there with those taken in Chowchilla, California, in the 1970s. A school busload of children were kidnapped in Chowchilla and was buried in the desert for several days. The children escaped and were physically unhurt. Sandall reports the Chowchilla schoolchildren were told to go home and forget about the incident, and that only a small percentage of them would suffer permanent psychological effects. A follow-up study 5 years later found 100% with psychological problems as a result of their experience. Sandall described the steps taken in Wyoming to provide opportunities for children and faculty to discuss their feelings after a bombing incident at school. School was held the day after the bombing and all who could be released from the hospital were encouraged to attend. Sandall commented in part, "Those children who verbalized most effectively and in the greatest quantity have managed recovery best" (1986, p. 2). Common reactions by children who have witnessed a traumatic event, according to Pynoos and Eth (1986), are (a) reexperiencing the event through thoughts; (b) fearing that it will happen again; and (c) withdrawing from the outside environment and experiencing an extreme need to cling to family members.

Schulman (1986) discussed immediate steps taken in Concord, New Hampshire, to deal with emotionality following the Challenger shuttle disaster that killed Christa McAuliffe, a teacher at the high school. Schulman emphasized that having a crisis team already in place was of great benefit. Students and teachers were provided many opportunities to express their emotions and were given flexibility with regard to their schedule and movement around the building. Students had a number of choices: They could go to the gym and vent frustrations and anger through physical activity, they could go to the cafeteria to support and be supported by others, or they could go to the library, which was a quiet work area.

Tertiary prevention involves the long-term follow-up of those affected by a crisis. Sandall (1986) stressed the need for tertiary intervention and pointed out that counseling was provided over the summer in Cokeville, Wyoming. Follow-up questionnaires are also recommended. School psychologists are in a position to provide follow-up and monitoring to those most affected by a crisis. If we cannot provide the long-term assistance ourselves, we can recommend that the family seek it privately. Anniversary dates of losses and crisis events are important.

Training Issues for Crisis Team Members

Team members need to be able to recognize a crisis, which Jay (1989) pointed out is an event that is likely (a) to interrupt normal routine and escalate in intensity; (b) to draw attention to the school and jeopardize the school's image; or (c) to interfere with the students' and the staff's ability to focus learning. Smead (1985) discussed the importance of responding immediately to a crisis to minimize effects. The crisis team should meet if at all possible even if a threatening event does not seem to be of crisis proportions. What this immediate response should be was emphasized by Slaikeu (1984), who outlined the following principles of psychological first aid:

1. Make contact with the victim and give him/her permission to express thoughts and emotions.
2. Explore the problem in terms of the past, present, and future.
3. Identify possible solutions to assist victim.
4. Take definite actions to assist victim.
5. Provide follow-up assistance.

Psychological first aid addresses immediate concerns and helps the victim sort out such needs as welfare, safety, shelter, and so on. Ruof and Harris (1988) recommend that team members receive as much as 30 hours of training.

Dealing with death. Stevenson (1986) pointed out that one of every 750 young people will die each year. The most frequent cause of death for school age children in order of magnitude are accidents, suicides, and homicides. School crisis team members need to be trained to assist in the aftermath of a death. Verification of a death is essential. A second or third verification needs to be made before the death is announced. The principal is the logical person to direct the crisis team and to announce the death. Fitzgerald (1988) makes a number of recommendations in this area:

1. Announce the death over the intercom so that everyone gets the same information; then visit as many classrooms as possible, especially those most affected.
2. Provide opportunities for discussion of emotions, the grief process, and funeral arrangements.
3. Send a letter home to parents giving information about the death and how parents can help their children.
4. Counseling grief groups may need to be provided on a continuing basis.

Pitcher and Poland (1992) recommend notifying teachers first about the specifics of the crisis through a calling tree or faculty meeting. A memorandum read to the students by the teacher is preferable to an intercom announcement. Educators often expect all children to react to a death in the same way, the typical expectation being that children should cry. Children should be given permission for a range of emotions. Children who state today that they don't care may cry tomorrow. Crabb (1982) suggested the following classroom guidance activities to assist students: (a) unfinished sentence writing; (b) drawing a picture to express feelings; (c) using music to express thoughts and emotions.

Do not rush to remove the desks and personal possessions of the deceased. Involve students in that process and encourage students to contact the family of the deceased in person or through cards and letters. It is recommended that a school psychologist follow the class schedule of the deceased. Stevenson (1986) recommends minimizing religious platitudes or symbolism and maintains that there is no correct response to a death. Physical contact may comfort some students. Students may be flooded with waves of emotions. The life history of each person will influence his or her ability to cope with the death. Stevenson states that it is appropriate to just let students sit but not to leave them unsupervised. The most common reaction is shock as students try to grasp the finality of the loss. It is important that all school personnel model expression of emotion; curriculum concerns may have to be set aside.

Oates (1988) recommends a model to determine the expected degree of trauma following a death. Oates points out that the popularity of the person who died and her or his length of time at a particular school are determinants. The circumstances of the death are also important. Suicide or murder result in more trauma than death by natural causes. A death that occurs at school also results in more trauma. These factors that address who, how, and where are very relevant to those dealing with death. It is also important to look at what other crisis events have impacted on a particular school population (Pitcher & Poland, 1992).

Team members will need to be advocates for giving school children and staff the opportunity to express their emotions. This point is illustrated by the following teacher comments: "I heard about the murder of R, a seven-year-old girl in my class the night that she was killed. I went to school early the next morning. My principal was just moving her desk out of my room. The principal said that all of her possessions had been removed and that I should avoid talking about her murder and concentrate on academics. I was angry and so were my students, we all felt robbed of a chance to express our emotions and to say our farewells to her. One student asked if we couldn't at least let a balloon ascend to heaven in her memory. I allowed that and it helped her classmates."

Crabb (1982) emphasized that children's emotional problems after a disaster continue until help is provided. Children need to be provided the facts in age-appropriate terms and rumors must be dispelled. Dillard (1989) recommended providing parents and children the opportunity to be together and share experiences after a tragedy. Dillard described meetings that were held over the summer following a shooting in Winnetka, Illinois. These meetings helped children achieve mastery of the shooting. Dillard stressed that a traumatic event is stored in active memory until mastered. Details fade from immediate memory when mastery occurs.

Implementing Crisis Intervention: Some Basic Skills

In implementing crisis intervention services in the schools, it is essential that school psychologists have the requisite skills. Unfortunately, many of our professional colleagues have not been systematically trained in crisis counseling and intervention. They may have implemented psychological first aid after a major crisis has occurred, but never received feedback on how to improve their competence nor been prepared prior to the occurrence of a traumatic event on how to respond to it.

As noted by Lazarus and Jackson (1993b, p. 16), "Disasters are inevitable. They can occur at any time, in any place. They can blindside anyone at any age. They hit communities large or small." Crisis will occur whether or not school psychologists are prepared; therefore, adequate training in crisis intervention is essential. This is fundamental to the model presented that emphasizes competent reaction to crisis and systematic prevention of crisis.

Crisis intervention has been defined as a "helping process aimed at assisting a person or family to survive an unsettling event so that the probability of debilitating effects (e.g., emotional scars, physical harm) is minimized, and the probability of growth (e.g., new skills, new outlook on life, more options in living) is maximized" (Slaikeu, 1990, p. 6).

This process can be conceptualized in two phases: first-order intervention, which may be thought of as psychological first aid, and second-order intervention, which may be termed crisis therapy. When school psychologists typically first arrive at a school that has experienced a crisis, they often offer immediate assistance. One type of first-order intervention is called debriefing.

Debriefing. The ability to conduct a debriefing should be considered a requisite skill for all school psychologists. Lazarus (in press-a) describes debriefing as "a process in which survivors or witnesses of a trauma have the opportunity to describe and discuss the impact the event had on their lives. It provides individuals an opportunity to tell their story, ventilate their feelings and have their emotional reactions validated." As explained by Lazarus and Howard (1993), the purpose of a debriefing is to help survivors regain some sense of control or mastery over their lives. It provides a forum to assist participants in predicting future events and reactions so that they can prepare for them in adaptive ways.

It needs to be emphasized that debriefing is not therapy (Bates & Freeman, 1992), though it is therapeutic. It may be better conceptualized as an educational and psychological experience designed to help participants "let some steam off the pressure cooker of disaster reactions" (NOVA, 1991, p. 147).

Debriefing can be conceptualized primarily as a *secondary level* of prevention according to Caplan's (1964) model. It emphasizes a quick response to a crisis in an effort to ameliorate long-lasting adverse effects. During the debriefing process, individuals most affected by a crisis can be identified for counseling, follow-up, and monitoring. Therefore, if done correctly, debriefing automatically leads into *tertiary prevention*. In some instances, the discussion of the impact of the trauma during a debriefing may later lead to policies, procedures, and practices designed to avert future crises. Therefore, debriefing may indirectly precipitate *primary prevention* activities.

An example will illustrate. Following a shooting on school grounds, the administration and faculty implemented specific written policies on what students should do if they suspect another student is carrying a weapon. Procedures were clearly articulated to assist students in alerting school personnel. An 11th-grade girl reported to the principal that a student was carrying a gun. She felt guilty about reporting, but told her friends that if she had not witnessed a previous shooting or participated in crisis counseling afterwards, she would have kept the secret to herself.

One of the advantages of conducting a debriefing is that it adds structure to a crisis, which helps contain the chaos and confusion. It can be comforting to administrators, faculty, and students to know that they will have the opportunity to discuss any crisis that occurs and be given the latest information. When conducted properly, a debriefing emphasizes open communication, honesty, and the expression of feelings. It can help being individuals together and assist in creating a support system.

In the same way that districts expect school psychologists to conduct psychoeducational assessments, they can expect that school psychologists be involved in crisis intervention. In this way practitioners can emphasize the essential nature of their services (Lazarus, in press-a). When school psychology positions are being threatened in tight financial times (see Steegmann & Harwood, 1992), this takes on added importance.

A Model for Debriefing

When conducting a debriefing, it is recommended that a structured model be followed. The National Organization for Victims Assistance (NOVA) has developed a model that can easily be followed by school psychologists. According to Lazarus (in press-b), training school psychologists in debriefing requires teaching the essence of active listening, empathy, and effective communication techniques. It also requires teaching the psychologist how to project a presence of competence, calmness, and compassion in the presence of confusion. The details of the NOVA model include team roles, ground rules, timing and logistics, and procedures and processes.

Team roles. The debriefing team consists of a minimum of two individuals, a leader and a scribe. If resources are available, then optional caregivers are recommended.

School psychologists can act as the debriefing *leaders* and assume the major responsibility for conducting the sessions. They introduce themselves and all team members and express sadness about the impact the trauma has had on the lives of the participants. They clarify the purpose of the debriefing and explain the ground rules. They give permission for all individuals to express their feelings and come and go as they please. If time is allowed, they may also discuss issues such as common reactions to crisis, coping mechanisms, long-term stress reactions, hints for coping with acute and chronic stress, and strategies for maintaining physical and emotional well-being.

The *scribes* provide emotional support to the debriefing leaders. Typically, they act as recorders by writing on a flip chart or blackboard the reactions and emotions of the group. They assist individuals in crisis by distributing kleenex and water, providing physical comfort when necessary, and helping individuals leave the room. Usually, they act like a supportive and unobtrusive partner contributing only when called upon by the group leader. Lazarus and Phelps (1993) emphasized that responding to crisis is a team effort: The leader, the scribe, and the caregivers are members of a team that need each other to function more effectively. By modeling this behavior, a set is stressed that participants should also rely on each other in a time of crisis.

Ground rules. The ground rules for debriefing are simple and straightforward. All communication is confidential: Nothing said during the debriefing leaves the room. Names of participants are not written down and the blackboard is erased or the flip chart pages destroyed after the session is over.

If individuals are willing, they may identify themselves when they speak. They are given permission to express how they feel. Participants are informed that this is not a critique of what happened, but instead a review of their reactions (NOVA, 1991). Carnes and Sorensen (1993) who conduct debriefings for emergency medical personnel, firefighters, and police officers also offer some suggestions that could be incorporated in the school setting. They emphasize that no one talks for another and that participants' should comment only about their own thoughts, feelings, and reactions. Mental health professionals who conduct debriefings advise that groups should be as homogeneous as possible. If individuals feel uncomfortable with anyone present, this will be deleterious to the process. Therefore, no school administrators or teachers should be present when students are debriefed. Most importantly, the media must be excluded from any debriefing involving students or school staff. If necessary, the media can be debriefed as a separate group.

According to NOVA (1991), there is both an announced and real agenda. The announced agenda is to ask participants now they have reacted, how they are all presently reacting, and what their expectations are for the future. The real agenda is to help the groups "define the crisis reaction, provide some crisis intervention and predict and prepare the groups for possible future events" (Lazarus, in press-a).

Timing and logistics. Debriefing should take place 24–72 hours after a trauma and should not interfere with events such as funerals and memorials. Day debriefings are usually better for students and school personnel. Night or weekend debriefings may be better for parents. Session should last no more than 2 hours.

As to logistics, the room needs to be accessible and comfortable. Debriefings should be conducted in a circle or horseshoe arrangement and need to be free from distractions and interruptions. Kleenex, water, and other necessities need to be available to all participants.

Process and procedures. Participants are asked to describe their experience during the crisis. Though participants are encouraged to speak as freely as possible, they should not be pressured to talk, and their privacy needs to be respected.

Typically, participants are asked specific questions such as: (a) where they were when the trauma occurred; (b) who they were with; (c) what they heard, smelled, tasted, or touched at the time; and (d) how they reacted.

According to Lazarus (in press-a), the leader listens to the reactions and underscores any statements that fit within the crisis reaction framework. The scribe writes down the emotions and recollections as they are generated from the discussion. Typically, recollections of any crisis may generate feelings of shock, disbelief, and denial. Further, reactions of anger and rage, fear and terror, grief and sorrow, confusion and frustration, and guilt and self-blame usually emerge. All throughout the process, the leader needs to listen and validate key emotional reactions and concerns.

Carnes and Sorensen (1993) describe the debriefing process as consisting of a series of phases. In practical terms, they are not distinct and include the intermeshing of these phases: (a) introduction; (b) discussing of facts, thoughts, reactions, and symptoms; (c) teaching; and (d) reentry.

The process can move from the introduction of the purpose of debriefing to the discussion by participants of the facts, and their thoughts, reactions, and symptoms related to the crisis. Near the end of the session, the leader can discuss issues such as coping with crisis and how to handle stress reactions. Effective strategies used by participants in handling crisis are validated. Future meetings at the school may be arranged as necessary.

Handouts may be distributed that provide information about crisis reactions and managing acute and chronic stress, and hints for maintaining physical and emotional well-being following a crisis (see Lazarus, 1992a). Authors such as Faberos and Gordon (1981), NOVA (1991), and Pitcher and Poland (1992) provide suggestions that are useful for creating handouts. Also, most school districts have available information that can be shared with participants. Organizations including Mothers Against Drunk Driving (1990) provide handouts for dealing with death at school. NASP also has made available brief handouts with such titles as Understanding Trauma and Grief and What to Do About It (Hyman, 1992) that are included in *Helping Children Grow Up in the 90s: A Resource Book for Parents and Teachers* (NASP, 1992).

Staff debriefing. Following a debriefing conducted by school psychologists, counselors, and mental health personnel, it is incumbent on the team to be informally debriefed. Staff need to ensure that they make time for themselves to go over the event and describe their own emotions and reactions. Anyone who has performed crisis intervention services knows that it can be an emotionally draining experience.

At the next team meeting, it is recommended that the group make a brief presentation to all members of the school psychology staff. One of the purposes of this presentation is to brainstorm ways to improve crisis intervention service and be better prepared for the next event.

One District's Approach to Crisis Intervention Planning

The development and implementation of a crisis intervention plan by one school district was assigned by the superintendent to psychological services. The following steps were taken:

1. The literature was surveyed and a few crisis plans from other school districts were located.

2. Principals were interviewed to get their input and to involve them in the process.

3. Directors of security, nursing, transportation, and public information were all interviewed.

4. A building crisis team approach was recommended with district personnel involved in a support role.

5. Building principals were designated as crisis coordinators and the media spokespersons. An in-service was provided to clarify their role.

6. Principals designated liaisons in the following areas: counseling, law enforcement, student, parent, campus and medical. These liaisons together with the principal formed the building crisis team. Training was provided to the various liaisons.

7. Principals were provided with training on dealing with the media, emphasis being placed on being cooperative but also containing the media.

8. District transportation personnel received training.

9. A tip sheet for teachers and aides for dealing with a crisis was developed and presented at an in-service in every school building. Teachers were encouraged to make plans to deal with such behavior as tantrums, fights, running away, and medical emergencies. A worksheet to address these was provided.

10. A basic premise emphasized was that this was a starting point and that the most important recommendation was for the building crisis teams to meet regularly and discuss their school.

11. Crisis intervention activities were publicized and shared with the community.

Crisis drills. The district had on paper an excellent crisis plan, but to make crisis intervention an integrated part of school more steps had to be taken. The superintendent authorized conducting crisis drills and gave the principals forewarning. A script for the initial crisis drill was written and various central administrators went to the mock scenes to role-play the crisis. To minimize school disruption the crisis drill took place outside the school building. A sample crisis scenario appears below.

> **Incident:** A female student has been shot in the foot by a pistol in front of the school by the flagpole. The pistol, which she had been carrying in her purse, discharged with students nearby. Your first notification of the incident is when several hysterical students rush into the office. The student has a younger brother who attends the same school. The superintendent's secretary will role-play the mother; please call her.
>
> **Task:** Please respond to this incident, following the district crisis intervention procedures. District personnel are on the scene to role-play and ask questions. This is a *practice drill* and district personnel should be alerted; however, it is *not necessary* to notify agencies outside the district.

Verbal and written feedback were provided to the crisis team. The importance of a team effort was stressed, along with indications of prior planning. The first two drills were videotaped and were shown at the principal's meeting. Numerous drills have since been conducted, including even a surprise crisis drill at the central office. No one has complained about the crisis drills and they serve the purpose of making crisis intervention a regular part of conducting school.

Improving Crisis Intervention Services

One of the best ways to improve crisis intervention services is to receive systematic feedback on the functioning of the crisis support team in delivering services to the schools. Broward County (Florida) schools has developed an evaluation team follow-up procedure that evaluates their effectiveness. In particular, these questions are asked:

1. Did the crisis support team (CST) assist you in developing a school-based plan of action for dealing with a crisis at your school?
2. Did the CST assist you in informing students (i.e., announcements by principal, etc.) about the crisis?
3. Did the CST assist you in informing parents (i.e., letter, etc.) about the crisis?
4. Did the CST provide assistance in communicating with the media?
5. Did a member of the CST assist you in meeting with members of your faculty?
6. Did the CST provide individual consultation services to teachers? If so, did that service assist teachers in dealing with the crisis?
7. Did the CST provide counseling to students individually or in groups? If so, did that service assist students in dealing with the crisis?
8. Did the CST provide follow-up services to students and staff in need of that service?
9. Were on-site materials provided by team members effective in dealing with the crisis?
10. What else could have been done to improve the team's effectiveness and helpfulness?

Moreover, crisis teams need to systematically document all their activities, including both individual and group contacts and their impression of the crisis and their interventions. By doing so, they can not only organize their services better, but also maintain a method for improving their delivery system.

Responding to Community Disasters and Schoolwide Crises

Within the past decade, the role of the school psychologist has changed, and it is now incumbent on our profession to provide leadership in the wake of disasters resulting from natural, social, or specific school district causes. As noted by Lazarus (in press-a), "disasters are inevitable. Appropriate preparation is not." Therefore, our profession needs to be better informed about crisis reactions, crisis theory, and crisis interventions in the aftermath of large-scale disasters.

A brief overview of postdisaster crisis intervention. As summarized by Cohen (1982, 1986, 1990), mental health journals and books are presenting theoretical formulations on stress effects and crisis theory and providing information on a variety of approaches that have been applied to postdisaster situations. Tyhurst (1951) originally pinpointed sequences and phases of behavior related to crisis resolution and began to specify intervention approaches applicable to each phase. Parad and Caplan (1966) described the mechanisms families used in adapting to crisis events.

R. Lazarus (1966, 1980) has expanded the knowledge of coping by identifying the significant role of the cognitive system as it affects the psychological interpretation of a trauma. He sees coping as defined by two major activities. The first involves changing the system — problem solving. The second involves managing the subjective components (feelings, thoughts, physical well-being, behavior) of the problem. A crisis state is characterized by a breakdown in these processes in which rational problem solving is difficult and the individual has difficulty managing the subjective components of the crisis situation. Horowitz (1986) has proposed a model of information processing for dealing with the aftermath of a tragic event. As discussed by Dillard (1989), Horowitz explained that until a traumatic event can be mastered through understanding and then integrated, its psychology is stored in active memory. As mastery occurs, the trauma is incorporated, the details fading from immediate memory. Until the mastery occurs, individuals are vulnerable to psychological overload such that normal ego coping mechanisms are not up to the stress produced by the disaster.

In dealing with children, Caplan (1964) views the prevention of mental disorders as a function of whether they have adequate physical, psychological, and cultural supplies for dealing with life's stresses. Children who are said to cope well following a crisis are those who have not only personal and psychological strengths, but also the social supports necessary for enduring disequilibrium and making appropriate accommodations.

Pynoos and his colleagues have studied life threat and posttraumatic stress in school-age children (Eth and Pynoos, 1985; Pynoos et al., 1987). They have provided strong evidence that acute posttraumatic stress occurs in school-age children within weeks of a life-threatening violent event. Age, sex, and ethnicity do not influence the type or severity of posttraumatic stress. The most important variable in relation to the number of posttraumatic symptoms reported appears to be the degree of exposure. This notion of proximity to the event as the most important variable has also been supported by Dillard (1989).

Many of the original formulations about crisis theory and intervention have come from researchers with a community psychology orientation who have studied adults. Recently, the school psychology literature has paid attention to the role of their practitioners in crisis intervention. Pitcher and Poland (1992) have effectively discussed what lessons can be learned from man-made school district disasters (Chapter 5). Here they discuss the traumas (also dealt with in the sources cited in parentheses) of Chowchilla, California (Terr, 1983); Cokeville, Wyoming (Sandall, 1986; Stevens, 1989); Winnetka, Illinois (Dillard, 1989; 1990); Greenwood, South Carolina (Greer, 1988; Stevens, 1990); and Stockton, California (Armstrong, 1989). A series of articles in the *Communiqué* has highlighted the role of school psychology staff in responding to natural disasters such as the San Francisco earthquake (Spicher, 1989), Hurricane Hugo (Alderman, 1989; Harlom, 1989), and Hurricane Andrew (Lazarus, 1992a; Lazarus, 1992b; Lazarus & Howard, 1993; Lazarus & Jackson, 1993a). Since there has been an unfortunate escalation in the number of crisis events, our profession has had to respond by focusing on crisis intervention activities.

Recommendations for dealing with stress in the schools following a natural disaster. Considerable research suggests that a fair percentage of children exposed to natural disasters will experience circumscribed, time-limited fears or behavioral problems (Auerbach & Spirito, 1986, p. 194). As noted by Pynoos et al. (1987), those most exposed will be the most vulnerable. In major disasters, such as that in parts of South Dade County that were directly hit by Hurricane Andrew, it has been estimated that 95% of the children experienced post-traumatic stress disorder (PTSD) symptomatology.

In treating the trauma of disasters, some points can be emphasized.

1. The family can be considered the first line of defense in helping children adjust. Benedek (1979), in reviewing the relevant literature, concluded that a caring and stable parent was probably the most essential element in a child's adjustment following a catastrophe. Raphael (1975) believes that family ties, reassurance, and open discussions are critically important elements.

2. Children separated from their families during a disaster will require a great deal of comfort and reassurance. Information about the family's well-being, phone calls, and so forth, should be provided as quickly as possible.

3. Disaster treatment and services mandate that professionals working with survivors of disaster seek out individuals in need rather than waiting for them to seek help. It has been noted by Tuckman (1973) that reaching out to disaster victims immediately after a trauma can minimize the development of post-traumatic symptoms.

4. School-age victims of a disaster should be encouraged to resume many of their daily activities. Children should also develop an understanding of their situation and confront rather than deny their thoughts and feelings. Crabbs (1981) emphasizes that activities should provide opportunity for personal expression regarding the crisis event.

5. Schools can provide a bridge to the community and serve as a disaster assistance center. The school can provide a site that can help coordinate disaster relief. Information of legal, economic, insurance, food, health, shelter and safety issues can be disseminated by school staff, crisis workers and community volunteers.

6. The school can provide security and support to children whose lives were disrupted by a natural disaster (Lazarus & Howard, 1993). Here school psychologists and counselors can provide needed emotional support to children and their parents.

7. It is also important to remember that children are resilient (NIMH, 1975–1984) and that victims view themselves as anxious and under stress but not pathological.

Some lessons learned. On December 3, 1985, and January 28, 1986 Concord (New Hampshire) High School sustained two significant tragedies. The first occurred when a 16-year-old former student who had recently dropped out of school appeared at Concord High carrying a loaded shotgun. After taking students hostage and threatening school personnel, he was killed in an exchange of gunfire with the local police. Less than 2 months later, Christa McAuliffe (the first teacher selected for a mission in space) was killed in the shuttle disaster along with six astronauts. Mrs. McAuliffe had been a teacher at Concord High until her NASA appointment. The faculty and students were watching on television the shuttle launching in which she died.

Norman Shulman had been the Emergency Service Program coordinator and was involved in developing the school's response plans following both crises. In discussing the best way to achieve the objectives of intervention following major stressful events, Shulman (1990, p. 67) proposes some intervention responses that can be deemed useful in almost any school situation following a disaster.

1. Obtain, disseminate, and update information about the crisis.

2. Encourage ventilation about the event in an empathetic and accepting manner.

3. Strengthen awareness of the normalcy of the victims' reactions. Help them view themselves as normal individuals undergoing acute stress.

4. Help the victims accept and confront the reality of the event. Identify reality-based cause–effect relationships between events and reactions.

5. Arrange group discussions to relate thoughts and feelings about the impact of the trauma.

6. Resume activity to help reorder life in its new context as it is redefined by the disaster.

7. Explain to victims that certain reactions, though distressing, are to be expected, and that these, as well as specific symptoms, should be viewed as normal.

As a final thought, by reading the literature on crisis theory and crisis intervention, by serving on crisis response teams, and by continually updating their skills through in-service and consultation with colleagues, school psychologists will be in a position to offer significant help following a major disaster. However, it is important that school psychology service staff work with their district to develop plans to cover a wide range of traumatic events.

SUMMARY

There has been an increase in the number of crisis events that affect the schools. School psychologists are the logical personnel to respond. It is important that school psychologists respond to this opportunity to help all concerned and to broaden the role of school psychology. The initial intervention of school psychologists will be at the secondary or tertiary level. It is important that we advocate for opportunities for those who experience a crisis to express their emotions. The focus for the future needs to be on primary prevention activities in the schools. Crisis intervention is an area in which all our efforts need to be constantly improving and evolving in response to the needs of our schools and society.

There are numerous state and national initiatives that focus on school crisis and violence prevention. A national educational goal has been set to have violence-free schools by the year 2000. The Clinton Administration has just passed the Safe Schools Act of 1993 to provide federal grants to encourage schools to develop curriculum, safety, and security programs. One state, South Carolina, has passed legislation that requires schools to develop crisis plans. It is our belief that schools will be held increasingly accountable for crisis prevention and management plans. The single greatest resource for school psychologists in this area is the National School Safety Center (NSSC), which is a combined effort of the United States Department of Criminal Justice and Education. The NSSC published articles, newsletters, journals, and books on all aspects of school safety. The current director of the NSSC, Ron Stevens (1990) emphasized that school crisis planning is an inside job that involves the staff, students, and community.

The importance of making crisis prevention and management plans today cannot be overemphasized. A biblical quote illustrates this point: "I must work the works of him that sent me while it is day: the night cometh when no man can work" (Gospel of St. John, Chapter 9, Verse 4). We have been faced with crisis situations and have found it difficult to think clearly and we have been uncertain of who should do what. School psychologists must step forward to provide leadership in crisis planning and should seek out those who need our help after a crisis.

Publishes resource papers, workbooks, and guidelines on school safety.

Pitcher, G., & Poland, S. (1992). *Crisis intervention in the schools.* New York: Guilford.
The authors discuss both theoretical and practical aspects of managing crises in the schools. The role of the psychologist ranges from that of consultant to trainer to provider of direct services. Practical information regarding staff in-services, managing organizational crises directly, and stimulating intrasystemic change is presented. Special emphasis on moving the system in the direction of providing preventive services is emphasized.

Best Practices in Suicide Intervention

Scott Poland
Cypress-Fairbanks (Texas) Public Schools

OVERVIEW AND SCOPE OF THE PROBLEM

Completed Suicides

Much has been written about the increasing numbers of suicidal youth and of completed suicides. It is important that school psychologists have accurate information about the extent of the problem. The Center for Disease Control (CDC) in Atlanta, Georgia, compiles data on suicides and publishes reports annually detailing the incidence rates by age categories and state of residence.

Berman and Jobes (1991) pointed out that the suicidal behavior of young people over the past 30 years has generated a great deal of public concern. They emphasized the high suicide rate for young people between the ages of 15 and 24. Specifically there has been a 312% increase in the youth suicide rate from 1957 to 1987 for youth ages 15 to 19. The CDC (1992) pointed out that the youth suicide rate remains at or near an all-time high. Over the past decade suicide has been either the second or third leading cause of death for young people. The leading cause of death for young people has remained accidents with suicide and homicide exchanging places from year to year. In 1992 the CDC listed suicide as the third leading cause of death for youth under the age of 19.

Suicide rates vary by age, sex, and race. School psychologists are logically the most concerned about the suicide rate for school-age youth 5 to 19. Suicide rates are reported per 100,000 for each age range. The United States had 30,906 completed suicides in 1990 of which 4,869 or 13.3% were completed by young people ages 15 to 24 with an incidence rate of 12.4 per 100,000 (National Center for Health Statistics, 1993). Berman and Jobes (1991) cited an incidence rate of .98 per 100,000 in the 10 to 14 age group, and no incidence figures for youth under the age of 10 reported for the same year, 1989. A national goal has been set to reduce the youth suicide rate by the year 2000 but there appears to be little progress and Pfeffer (1986) predicted a 94% increase in the 15- to 19-year-old category by the year 2000.

Suicidal Ideation

This chapter's author (Poland, 1989) reviewed a number of national surveys of high school students. They indicated that, across the nation, between 8% and 14% of all high school students reported an attempted suicide and 25% to 35% admitted to suicidal thoughts. The CDC (1992) found the following data on high school students:

- Eight percent had already attempted suicide.
- Twenty-seven percent had seriously contemplated it.
- Sixteen percent had made a plan to commit suicide.

Davis and Sandoval (1991) reviewed figures on incidence and attempts and estimated the following prediction for a high school of 2,000 students.

- One suicide every 5 years.
- 168 to 400 annual attempts.

There is not much information available on the extent of suicidal ideation of elementary- and middle-school-aged students. My earlier report (Poland, 1989) indicated that the suicide of young people under the age of 10 is rare and the most cited explanations for lower incidence when compared to adolescents are:

- Less depression, alienation, and loneliness.
- More involvement with parents.
- Less drug and alcohol involvement.
- Less access to firearms.

School psychologists are encouraged to become familiar with incidence figures from their county and state. It is also important to be aware of racial and regional differences in suicide rates. Suicide rates are higher in western states of the United States which have a high Native American population. Leenaars and Wenckstern (1991) also pointed out that many researchers feel that governmental figures are actually an underestimation of the problem. Added to that is the fact that schools can be greatly affected by the suicides of individuals other than students such as a parent, teacher, neighbor, or sibling (Poland, 1989).

BASIC CONSIDERATIONS

Youth suicide has many implications for the schools. Laws in 12 states address the role of the school in prevention (Nguyen & Siver, 1993), and most states are studying the problem of youth suicide. No national legislation has been passed although the federal government sponsored a national conference in 1985. The strongest proponent for national legislation has been U.S. Representative Ackerman (1993) who emphasized that the federal government must fund youth suicide prevention efforts and encourage cooperation at all levels of government.

The question of the responsibility of the schools with regards to youth suicide is not a new one. Stekel, a social scientist, commented on an outbreak of youth suicide in Europe in the early 1900s, "The school is not responsible for the suicide of its pupils, but it also does not prevent these suicides. This is its only, but perhaps its greatest sin" (quoted in Peck, Farberow, & Litman, 1985, p. 158). Few schools are prepared to deal with youth suicide, and not enough policies and procedures have been written to clarify the role of school personnel (Harris & Crawford, 1987; Poland, 1989). Ross (1985) stressed that it is fear and not lack of concern that results in school administrators being reluctant to work on this problem. Few school administrators have received any formal training in suicide prevention. They believe many misperceptions about youth suicide and see it as a problem that happens elsewhere.

School prevention programs began in California in the 1970s and have spread by a grassroots effort with each school re-inventing the wheel (Ryerson, 1988). It is evident that school psychologists are the first professionals school personnel are going to turn to when they feel that a student might be suicidal. Davis and Sandoval (1991) cited one study that found that 79% of teachers would turn to the school psychologist first for assistance. Therefore, school psychologists are in a position to clarify the schools' role and write policies and procedures to work on this problem. Several writers emphasize that intervention programs in the school are effective (Cantor, 1987; Guetzloe, 1989; Leenaars & Wenckstern, 1991; Ross, 1985; Ruof & Harris, 1988.

Case Example

A high-school English teacher read a theme by a ninth-grade girl containing many references to hopelessness and nonexistence. The teacher asked the girl to stay after school and directly inquired about how things were going for her. The girl shared many family, school, and romance problems that were bothering her. She stated, "My life is hopeless and not worth living." The teacher told her that help was available and that the teacher cared. The teacher escorted her to the school counselor's office. The school counselor spent a lot of time establishing rapport with the student and gathering a careful case history. The girl had attempted suicide 6 months ago by taking aspirin. She became ill but told no one what she had done. The girl's aunt had committed suicide by carbon monoxide poisoning, and the girl planned to utilize that method next time. She had carefully thought out when she could go into the garage without being detected and had imagined how others would react to her death. The school counselor called the school psychologist for assistance. The girl signed a no-suicide contract and was told that her parents would be called and that this was in her best interest and in accordance with school policy. She was told that many other students had been helped and that the school psychologist and counselor would solicit a supportive reaction from her parents.

The parents initially refused to come to school. When they did arrive, they were angry at their daughter for not telling them about her suicidal thoughts. A referral was made to a private practitioner who had experience working with suicidal teenagers. The parents were provided with specific suggestions about supervision and support of their daughter. A follow-up appointment was made at school with the student and the school counselor. The principal was informed of the situation and the referring teacher was complimented on her role. The girl was monitored closely over the next several years. She never attempted suicide again. Shortly before graduation she stopped in and thanked her English teacher for helping her. The student stressed that her life was not wonderful but she was glad to be alive.

Forces and Factors in Youth Suicide

Space does not permit a detailed examination of the numerous forces and factors that school psychologists need to be aware of (see, instead, Poland, 1989).

However, the following section indicates the major events and circumstances in youth suicide. A precipitating event may cause a young person to act on suicidal thoughts. The most common precipitating events involve arguments with parents, boyfriends or girlfriends, or the loss of a loved one (Eyeman, 1987; Porter, 1985). Shaffer (1988) stressed that discipline incidents and loss of face with peers are also factors.

Depression has long been considered the most important warning sign of suicide. Numerous researches stress that depression in children does exist but does not account for all youth suicides.

Conduct disordered adolescents are also at risk to commit suicide (Eyeman, 1987; Shaffer, 1988).

Substance abuse is now known to play an important role in youth suicide. Substance usage may cause a young person to lose contact with reality and increases the chance of a suicide attempt. Alcohol and many other drugs are depressants which only add to a young person's problems. Davis, Sandoval, and Wilson (1988) suggest that substance abuse be added as a major warning sign of suicide.

Students who run away also may be at risk for suicide. Researchers have found that runaways attempt suicide approximately 20% of the time (Engleman, 1987; Fortinsky, 1987).

How children develop their concept of death is important. The young child may view death as something that is either reversible or only happening to the very old (Davis, 1985; Pfeffer, 1986). Adolescents may also have some misperceptions about the finality of death. Young children who talk about life-threatening, risk-taking behavior need to understand the possibly fatal consequences. The school psychologist should inquire as to the beliefs that the suicidal young person has about death. The young person who has spent lots of time imagining the reaction of others to his or her suicide may be at high risk to commit suicide (Davis, 1985; Poland, 1989).

Some youngsters' suicidal behavior is attention getting and manipulative. Barrett (1985) stressed that parents need to recognize that the young person wants something to change and parents should let themselves be manipulated until they get professional help.

Other factors that may greatly influence a particular child include:

1. Suicidal statements or suicide attempts by a parent.
2. Motion pictures that deal with suicide.
3. Suicidal song lyrics.
4. News coverage that glamorizes or mysticizes a suicide.

There has been a dramatic change in the methods employed to commit suicide by young people. Females are increasingly committing suicide by using guns. A strong correlation has been found between gun ownership and suicide with guns involved in approximately 60% of all suicides (Lester, 1988; Loftin, C., McDowell, D., Wiersema, B., & Cottey, T. 1991). The dramatic three-fold increase in youth suicide since the 1950s is almost entirely attributable to the increase in suicide by firearms according to Perper, Allman, Moritz, Wartella, and Zelenak (1991). Many professionals believe the single greatest factor to reduce youth suicide would be decreasing handgun access to troubled youth. Loftin et al. (1991) cited growing research demonstrating that handgun control legislation reduces the youth suicide rate. The CDC (1992) reported that none of the youth suicide prevention programs surveyed addressed restricting access to guns despite the evidence of its effectiveness. School psychologists will be in a position to address gun availability with young people and their parents and need to be specific about the need to remove guns from troubled youth. One teenager in her good-bye note to her parents questioned why they made suicide so easy by leaving a gun available (Poland, 1989).

There is no single factor or cause that explains youth suicide. Siebel and Murray (1988) stress that there may be as many as 28 factors or causes. School personnel need to be aware of these factors, and if at all concerned about a particular student, they need to inquire further.

BEST PRACTICES

Developing a Suicide Intervention Program

Every school system needs a written policy to clarify the school's role. These procedures need to address the three levels of intervention outlined by Caplan (1964) and elaborated on by Poland, Pitcher, and Lazarus in the chapter in this volume on Crisis Intervention. These three levels — primary prevention, secondary intervention, and tertiary intervention — correspond well with the terms utilized in the suicidology literature of *prevention*, *intervention*, and *postvention*. Vidal (1986) stressed that help for a suicidal student is contingent on school personnel knowing the policy. The obligations of the school at a *minimum* are (see Poland, 1989, for more detail):

1. Detect suicidal students.
2. Assess the severity level of their suicidal symptoms.
3. Notify parents.
4. Secure the needed mental health services and supervision for the student.
5. Follow-up at school.

Detection

All school personnel including bus drivers and aides need information on the warning signs of suicide as identified by the American Association of Suicidology (AAS; 1977). These warning signs include the following verbal and behavioral clues:

1. Suicide threats or statements.
2. An attempt at suicide.
3. Prolonged depression.
4. Dramatic change of behavior or personality.
5. Making final arrangements.

School personnel should be encouraged to reach out to help suicidal students and should follow district policy in referring students. School personnel *must not* keep a secret about suicidal behavior and need to understand the situational nature of youth suicide. They should feel empowered that they could save a life as in the case example.

Assessment

School personnel must be skilled at assessing the severity level of a suicidal student's symptoms. The most logical personnel to do this are school psychologists. They need to be prepared for whenever suicidal issues may come up by working through personal issues and perceived inadequacies in this area and by investigating the various suicidal assessment scales. It may be advisable to rehearse with a colleague or even a drama student intervening with a suicidal individual.

There is no one scale or set of questions recommended for use with a suicidal student. Davis et al. (1988) reviewed the available instruments. Although they cautioned that more validation needs to be done, they noted the following instruments as the most promising ones:

1. The Hilson Adolescent Profile developed by Inwald, Brobst, and Morrisey (1987).

2. The Suicidal Ideation Questionnaire developed by Reynolds (1987).

3. The Suicide Probability Scale developed by Cull and Gill (1982).

Hoff (1978) questioned the effectiveness of lethality assessment scales and instead stressed communication and the establishment of rapport with the student. Barrett (1985) emphasized the importance of carefully gathering information from the student to guide actions and pointed out the distinction between assessment and prediction. McBrien (1983) stressed that practitioners must stay calm and ask a series of questions as if the student were planning a trip. The need for direct inquiry into suicidal thoughts and plans is essential.

A careful case history and thorough inquiry into the suicidal plans and actions can be outlined through sample questions (see Poland, 1989). A number of suicidal assessment scales classify students into the categories of low, medium, and high risk for suicide. The school psychologist needs to be careful not to categorize a student as low-risk based on the psychologist's need rather than on the information gathered from the student.

No-suicide contracts have been shown to be effective in preventing youth suicide. Figure 1 is a sample no-suicide contract. This type of contract helps the student take control over their suicidal impulses and reduces the anxiety of both the student and the school psychologist (Berman & Jobes, 1991; Davis & Sandoval, 1991; McGrien, 1983). However, contracts should not be used in isolation (Barrett, 1985). A student who refuses to sign a no-suicide contract should be supervised until parents can pick them up and hospitalization may be needed.

A number of assessment approaches were reviewed by Davis and Sandoval (1991). They emphasized the importance of school personnel following one of the available models and techniques which provide the practitioner with structure to follow in a very anxiety-provoking situation. They caution school personnel to recognize their limitations and cited research demonstrating the impulsivity of youth who committed suicide. School psychologists dealing with suicidal youth should seek support and collaboration from their colleagues (Poland, 1989).

Parent Notification

Parents must be notified any time it is believed that a child is suicidal. The question is not whether to call them but instead what to say to them. The goal of parent notification is to safeguard the welfare of the student. The school psychologist who notifies parents is also protecting himself or herself from liability. School districts and school employees have been sued for inadequate suicide prevention programs.

Slenkovitch (1986) has stressed that schools should never take a suicide threat lightly. Davidson (1985) and Henegar (1986) discuss the question of liability. They clarified the importance of one's duty to care and the foreseeability of a client's actions and stated that the primary issue is negligence. Henegar commented in part, "a negligence theory in a suicide case is not generally a claim that one caused the suicide but rather that one did not take reasonable steps to prevent it" (1986, p. 4). Henegar made several recommendations that have implications for school psychologists.

1. Increase supervision of the student.

2. Limit access to self-destructive instruments.

3. Obtain psychological treatment for the student.

Davis and Sandoval (1991) discussed several cases brought against the schools by the parents on the grounds that their child's death resulted from school personnel having inadequate training in suicide prevention. Texas has addressed this issue by recommending yearly training for all educators on the warning signs of suicide. It seems clear that school personnel need training and that parents must be notified when a student makes suicidal statements or engages in suicidal actions. A ruling by the Court of Appeals in Maryland held that school counselors may have a duty to intervene to prevent a suicide. The case involved a junior-high-school student who made

FIGURE 1. A sample no-suicide contract.

suicidal statements to friends. The case *Eisel versus Board of Education, Montgomery County, Maryland*, was discussed in detail by Owens (1992). Eisel, when questioned by school counselors, denied any suicidal ideation, and the counselors chose not to notify her parents. Eisel was murdered in a murder-and-suicide pact one week later, and her father filed suit contending that counselors were negligent in not notifying him. The Court of Appeals ruled that the counselors did have a duty to warn the father and should have been able to foresee the suicide despite Eisel's denial. This case was appealed and a recently completed 2-week civil jury trial found that the school counselors were not liable for the one million dollars in damages sought by the father of the deceases (Jennings, 1994). This case takes school personnel into new territory with regards to parent notification. The safest course of action would be notifying parents that you heard that their son or daughter was suicidal but that the statements were denied by the student. This case and many others illustrate the need to notify parents when in doubt and to keep careful records of interactions with suicidal students.

Most suicidal students will be relieved that their parents will now know what has been on their mind. Parental reactions may range from extreme cooperation to extreme denial and anger at the school. A common initial parental reaction is one of being hurt that their child is thinking of suicide. Johnson and Maile (1987) recommend that parents do the following:

1. Be patient, show love, and seek out the help their child needs.
2. Take threats and gestures seriously.
3. Keep communication open and get help with no strings attached.

The challenge to the school psychologist is to notify parents in a way that elicits their support and to convince the parents to obtain the needed services for their child. Stanton and Stanton (1987) emphasized finding parental strengths and empowering the parent with the belief that their child can be helped. It is advisable to document parent notification and to have two school personnel present at the conference where parents are notified. A resistant parent should be asked to sign a form acknowledging that they have been notified of their child's suicidal state (see Figure 2).

Parents who refuse to follow through on the recommendation for community treatment services need to be told that it is neglectful not to get treatment for a suicidal child and that school personnel will call the child welfare department. A resistant parent might forbid the school psychologist to talk with their child. Some states, such as Texas, have passed legislation that allows psychologists to provide services to a suicidal minor without the parents' permission.

Working with suicidal students causes anxiety. Brown and Schroff (1986) recommended that school psychologists take care of themselves by

1. Getting the opinion and support of others and processing feelings.

FIGURE 2. A sample notification of emergency conference.

I, or we ______________________________, the parents of ____________________________
were involved in a conference with school personnel on ____________________________.
We have been notified that our child is suicidal. We have been further advised that we should seek some psychological/psychiatric consultation immediately from the community. School personnel have clarified the district's role and will provide follow-up assistance to our child to support the treatment services from the community.

2. Recognizing that no one can assume the responsibility for the life of an individual who is threatening suicide.

The approach just described is only one aspect of youth suicide prevention described by the Center for Disease Control (1992). These activities fall in the category of what they refer to as School Gatekeeper Training. They also encourage that suicide prevention information be presented to parents and community members such as clergy, police, merchants, and recreational staff who are Community Gatekeepers. Peer Support Programs designed to foster competency, peer relations, and social skills are also recommended.

Community Services

School psychologists need to be familiar with community resources to assist suicidal students. A goal should be to establish a cooperative relationship between the school, the parent, and the community mental health provider so that maximum support is provided to the student. The school psychologist should not accept the primary responsibility of treating a suicidal student although he or she will need to continue to provide support and monitoring at school even though the student is receiving community services.

Summary of Intervention

The key points in the intervention process can be summarized as follows:

1. Try to remain calm and seek collaboration from a colleague.

2. Gather case history information from the student and approach the student as if he or she were planning a trip.

3. Ask specific questions about the suicidal plan and the frequency of suicidal thoughts and remove any lethal weapons.

4. Emphasize that there are alternatives and the student is not the first person to feel this way.

5. Do not make any deals with the student to keep the suicidal thoughts or actions a secret and explain your ethical responsibility to notify the parents of the student.

6. Have the student sign a NO-SUICIDE CONTRACT and provide the student with the phone number of the local crisis hot-line.

7. Supervise the student until parents have assumed responsibility. (Poland, 1994)

Postvention

Schools are frequently not prepared to deal with the aftermath of a suicide yet few events are more disruptive. Experts have emphasized that a series of planned steps must take place to minimize the chances of a second suicide and to help students and faculty deal with their grief (Kneisel & Richards, 1988; Lamb & Dunne-Maxim, 1987; Leenaars & Wenckstern, 1991). Postvention policies need to be in place prior to a suicide. Numerous writers have emphasized that the suicide must be acknowledged and discussed (Biblarz, 1988; Davis & Sandoval, 1991; Ryerson, 1988). Normal procedures in the event of a death should be followed with an emphasis on avoiding a dramatic, romantic, or mystic treatment of the suicide. The task facing most school survivors is grief resolution. Homeroom discussions need to provide an opportunity for students to express their grief. Lamartine (1985) pointed out that the suicide of a student increases the probability 300% that a second suicide will occur. School psychologists need to identify other students at risk to commit suicide and provide assistance to them. Everyone at school needs to know the warning signs of suicide and to feel empowered to prevent further suicides. The following postvention guidelines were developed by the American Association of Suicidology (AAS; 1991):

1. Don't dismiss school or encourage funeral attendance during school hours.

2. Don't hold a large-scale school assembly or dedicate a memorial to the deceased.

3. Do provide individual and group counseling.

4. Verify the facts and do treat the death as a suicide.

5. Do contact the family of the deceased.

6. Do emphasize that no one is to blame for the suicide.

7. Do emphasize that help is available and that suicide is preventable and everyone has a role to play in prevention.

The AAS Postvention Guidelines (1991) also contain a number of recommendations for the media. There is growing national awareness that dramatic media coverage of youth suicide may contribute to the cluster phenomenon. Specific AAS suggestions for the media are:

1. Avoid details of the method and front-page coverage.

2. Do not report the suicide as unexplainable or the results of simplistic causes.

3. Do not print a photograph of the deceased.

4. Include positive outcomes of suicidal crises and emphasize where suicidal youth may obtain help.

Youth suicide is not news in most of our large cities unless several suicides occur in the same school. The fact that it is not news is a blessing but a sad commentary on the times. Much is still not known about suicide clusters and contagion although the Center for Disease Control is in the midst of a several-year study.

School psychologists do need to know that not everyone agrees with guidelines developed by the AAS. In particular, recommendations made by the Phi Delta Kappa Organization (1988) are in conflict on key points. Phi Delta Kappa recommended that the death not be treated as suicide and suggested that all concerned be forbidden to use the word "suicide" in order to protect the privacy of the family. A school administrator who has not thoroughly researched this area might follow these guidelines which also call for having all students who want more information about the death to gather in a large assembly. This leads to dramatization and glorification of the suicide.

Curriculum Issues

Curriculum approaches to suicide prevention fall into two categories. The first approach emphasizes a positive school climate; affirms life; and promotes life skills for students, especially problem solving (Sowers, 1987). All professionals agree with the importance of this approach. The second approach involves directly talking in the classroom about suicide as a mental health problem (California State Department of Education, 1987). These classroom presentations emphasize the warning signs, befriending skills, friend intervention, and the situational nature of suicide. Also included are the relationship between suicide and substance usage and community services available to help a suicidal youth.

There is debate about whether such an approach is recommended. Shaffer (1988) and colleagues Vieland, Whittle, Garland, Hicks, and Shaffer (1991) called for a moratorium on such curriculum presentations and noted that they were developed because the schools felt a need to do something. Smith (1988) commented on Shaffer's research and noted that most students who participate in curriculum programs view them positively. Holtzman (1991) cautioned against prematurely stopping curriculum presentations to prevent youth suicide and emphasized the limitations of the research done by Shaffer and colleagues and that all concerned were upset about newspaper headlines that suicide preventive programs were harmful to young people. The central issue to this controversy seems to be that curriculum presentations somehow plant the idea of suicide. This point is at the basis of Schafly's (1985) objections to curriculum presentations. A logical question is, "Can teenagers translate information presented to them into life-saving behavior?" Numerous evaluators have said "yes" to this question.

The question of whether parent permission should be obtained prior to a student participating in a curriculum presentation has been raised as well as the relevance of the Hatch Amendment (Davis et al., 1988; Shafly, 1985). Florida requires parent permission, for example, while California does not. An unfortunate consequence of the curriculum debate is that many school districts have misinterpreted the debate to mean that professionals do not agree on schools needing to prepare and take systematic steps to prevent youth suicide. This is not the case and no debate exists about the basic role of the school in detecting and assisting suicidal youth.

School psychologists need to be involved in determining the need for curriculum presentation in their district and selecting materials if presentations are to be provided to students. My 1989 book describes in detail how a school psychologist can design a carefully integrated mental health unit on suicide which addresses the biggest professional frustration that friends always knew about the suicidal actions of the deceased but unfortunately did not look to adults for help. There is every indication that with adult professional assistance the majority of youth suicides could be prevented.

The Center for Disease Control (1992) reviewed curriculum approaches to prevent youth suicide and summarized the following research findings:

1. Participants had short-term increases in knowledge about suicide prevention and knew more about mental health referral sources.

2. There is no evidence of increased suicidal behavior on the part of program participants.

3. The highest risk is that students may react negatively, and school personnel should be ready to assist any student who finds the program upsetting.

CDC recommends that suicide prevention programs be incorporated into existing health curricula rather than a highly visible special program. Programs were typically only 1 to 3 hours in length, and professionals must be cautious about what can be expected from a brief presentation. No program surveyed sought to measure changes in behavior such as students referring themselves or friends for assistance.

SUMMARY

The problem of youth suicide is at or near an all-time high but is somewhat overshadowed by concerns about other problems that face young people today such as violence, drugs, poverty, teen pregnancy, and AIDS. Many of these problems are inextricably linked. School psychologists have historically not been trained in suicide intervention despite the fact that they are the first professionals school personnel turn to for assistance in this area. It is important that school psychologists provide leadership to help schools respond to the problem of youth suicide. The following recommendations from the Center for Disease Control (1992) should guide the actions of school psychologists.

1. School programs need to link up more with community resources.

2. More programs need to focus on reducing access to lethal weapons, especially guns.

3. To address high-risk youth, suicide prevention programs need to be linked with other programs such as alcohol, dropout, and pregnancy programs.

4. The lack of evaluative data on prevention programs is a great obstacle to improving prevention efforts.

5. Programs need to be developed to focus not only on school-aged youth but also on the 20 to 24-year-old population who have a suicide rate twice that of teens.

6. Schools need carefully written policies and procedures to address the problem of youth suicide, and school personnel need training on the warning signs of suicide.

ANNOTATED BIBLIOGRAPHY

California State Department of Education. (1987). *Suicide prevention program for the California public schools.* Sacramento: Author.

Provides the information needed to train school personnel to detect suicidal behavior. The lesson guide provided is appropriate to use in the curriculum for grades 9–12, emphasizing warning signs of suicide, community resources, and intervention by friends.

Pitcher, G., & Poland, S. (1992). *Crisis intervention in the schools.* New York: Guilford.
The authors discuss both theoretical and practical aspects of managing crises in the schools. The role of the psychologist ranges from that of consultant to trainer to provider of direct service. Practical information regarding staff in-service, managing, organizational crises directly, and stimulating intrasystemic change is presented. Special emphasis on moving the system in the direction of providing preventive services is emphasized.

Poland, S. (1989). *Suicide intervention in the schools.* New York: Guilford.
The role of the school is defined, and case examples provide step-by-step guidelines for setting up and maintaining a comprehensive program. Issues covered include forces and factors in youth suicide, assessment, parent notification, liability, legislation, curriculum, and dealing with the media. Detailed procedures for intervention following crises is provided.

Center for Disease Control. (1992). *Suicide prevention programs: A resource guide.* Atlanta: Author.
This resource guide was the result of a national networking effort to locate exemplary youth suicide prevention programs. Eight major prevention strategies are outlined with discussion of findings and recommendations for the future.

Poland, S. (1994). *Crisis intervention resource and training guide.* Author.
This guide gives a complete overview of all levels of crisis intervention and includes practical examples of program development. A variety of school crisis scenarios are covered in detail including suicide, violence, and gangs. This guide includes numerous overheads designed to assist school psychologists to give in-service presentations and help them develop district and building plans.

Davis, J., & Sandoval, S. (1991). *Suicidal youth: School-based intervention and prevention.* San Francisco: Jossey-Bass.
The authors review research and clinical practices in youth suicide. Guidelines are provided for determining suicide potential and developing suicide awareness school programs.

Focus on Individualized Services

School Psychologist as Problem Solver

Stanley L. Deno
University of Minnesota

OVERVIEW

Successful functioning in any role requires a clear image of the primary purposes of that role. A cursory review of the current literature in school psychology reveals that clarity of purpose is lacking in the school psychologist role (Kramer & Epps, 1991). While the primary purpose may not be clear, the predominant activity of school psychologists is easy to identify. Assessment — with its related ignominious responsibility as gatekeeper for special programs — remains the most conspicuous activity of school psychologists. The problem with restricting the role of school psychologist to that of psychometrician is that many school psychologists have broader training and interests and are eager to make a broader contribution to child and family development. In the present chapter a case will be made that a broader and more satisfying role for school psychologists is that of data-based problem solver.

Fostering Human Development as the Purpose of Schooling

In developing a conception of school psychologists as problem solvers consider first the context within which they work. As participants in school environments, school psychologists are committed to the general purpose of schooling, that is, facilitating human development. This means, of course, that school psychologists will embrace the cognitive, affective, social, and physical developmental outcomes around which schools are organized. Within this framework, the problems to be solved by school psychologists are those generated out of the schools' efforts to promote growth and development.

Intervention. If we view the purpose of schooling as fostering human development, we can cast the mechanism of schooling as intervention. The term "intervention" is appropriate in that society has vested educators with the responsibility to organize deliberate activities that affect the course of child development. Without the deliberate activities of schooling there is no doubt that the lives of children and youth would be markedly different. The term intervention, then, can be used very broadly to refer to the mechanisms of schooling. These interventions of schooling are designed to have impacts on the developmental processes that would otherwise occur in their absence.

Problems. Just as the term intervention can be used broadly to refer to the mechanisms of schooling, the term "problem" may be used to refer to the question of how best to attain the specific outcomes toward which interventions are directed. Thus, when schools focus their activities on developing literacy and numeracy, the problems to be solved are how best to promote the development of performance at reading, writing, and arithmetic. When schools seek to foster personal and social development, the problems to be solved are how best to promote the levels of development desired in these domains. When students take courses in physical education, the problems are how to best effect the physical development of children and youth. Societal priorities for the outcomes of schooling, then, establish the developmental problems that serve as the focus of intervention.

As should be clear in the foregoing paragraph, problem solving is not a term reserved for activities focused on atypical development. From the perspective presented here, problem solving is defined by the approach taken to intervention rather than by the perception of failure or deviance. We are problem solving if we conceptualize the primary goal of our work as reducing the difference between a current state of affairs (for example, the student's current level of development) and some future state of affairs (for example, his or her development at some later point in time). Taking such a generic approach is useful because it avoids controversies surrounding a question of whether a problem "really" exists. Further, from this perspective the school psychologist is in a position to work both proactively and reactively — enhancing as well as remediating — when intervening to foster human development.

The current state of affairs with respect to American education is a good example of how arbitrary the argument can be over whether educational problems exist. Some educators argue that the schools are more effective than they have ever been, while others both inside and outside of the schools believe that the United States is experiencing a major crisis. Obviously, whether the developmental outcomes currently attained by the children and youth of our country is viewed as satisfactory depends upon the standards applied by the person making the judgment. Many education professionals have experienced situations where they viewed a child's development as being quite satisfactory while the child's parents were quite unhappy because they wanted more.

Controversy over whether "real problems" exist can be reduced if education is viewed from a developmental perspective where all children and youth are seen to move at an irregular pace along various continua. Any child's current level of performance in some developmental domain always will be the focus of interventions designed to effect whatever movement along those continua is specified, and education's problem is to determine how best to accomplish that movement. Operating from this perspective, school personnel are problem solving whether they or someone else sees the child as developing "normally."

APPROACHES TO PROBLEM SOLVING

If school is a set of interventions designed to foster human development, and school personnel are problem solvers, what, then, is problem solving?

Typical Elements of Problem Solving

While a variety of different perspectives exist regarding the nature of problem solving, all contain three basic elements:

1. Formulating the problem.
2. Generating and selecting potential solutions.
3. Testing the selected alternatives.

These basic elements were contained in the conceptual model of human behavior developed by Miller, Galanter, and Pribram more than thirty years ago (1960). In their book, *Plans and the Structure of Behavior*, they describe a consistent structure of human activity across person–environment interactions. Their view is that humans interact with the world through successive applications of a sequence identified as Test-Operate-Test-Exit or TOTE. Tote, in effect, describes the basic steps required in problem solving. More recently, the IDEAL model of problem solving has been outlined by Bransford and his associates (1984). IDEAL is an acronym for the steps typically required in problem solving:

- Identify the problem.
- Define the problem.
- Explore alternative solutions to the problem.
- Apply a solution.
- Look at the effects of that application.

Inherent in both of these models is the idea that problem solving involves sensing and perceiving the existence of a problem, clarifying and defining the problem, generating and trying different approaches to overcoming the problem, and observing and evaluating the effects of our efforts.

School-Based Intervention Models

The intervention activities organized by the schools are of two general types. One is the ordinary set of instructional activities available to all children attending regular classrooms in their home schools. This common set of experiences is organized and conducted as the general education program. A second smaller set of interventions that exists in the school falls under the heading of special and compensatory programs. Different from the general education interventions, this second set of interventions is intended for only a subset of the general student population. Although it is possible to consider the role of school psychologist as problem solver within the context of both of these sets of school-based interventions, in the remainder of this chapter the focus will be on the problem-solving activities of the school psychologist within the context of special and compensatory programs.

The Role of Assessment in Problem Solving

When Miller, Galanter, and Pribram (1960) pointed out in their TOTE model that ordinary human interaction with the environment can be conceptualized as a sequence of problem-solving activities, they placed emphasis on the role of testing to determine the current state of the environment. As might be expected, while the word "test" was used to describe a key element in those activities, they used the term to refer to probing informally, rather than formally, and observing effects. Perhaps a general definition of assessment as "information gathering" for purposes of decision making is closest to the sense in which they use the term test within the TOTE model. In the same vein, Bransford's IDEAL model of problem solving includes the terms "identify" and "look at" to refer to the informal processes of sensing and perceiving aspects of the world that constitute the activities called informal assessment. Despite the fact that these activities are viewed as informal and natural elements of ordinary human problem solving, it is important to recognize the key role played by these informal assessment activities in problem solving. Because assessment is always viewed as a key part of school psychologist training, the role of assessment in problem solving will be considered next.

Assessment and Measurement Defined

The general definition of assessment as information gathering for purposes of decision making is inclusive of all types of information — qualitative or quantitative, verbal or numerical — gathered through all means — highly structured deliberate efforts involving intrusive test administration or informal and naturalistic observation. Narrative reports, anecdotal records, test scores, and coded observational data are all encompassed by assessment. The key element in assessment is neither the information gathered nor the procedures used, but what decision is to be made.

Measurement is a subset of assessment activities. The purpose of measurement is a numerical description and representation of observations. Those observations can be organized and structured through activities called tests or through activities occurring in natural settings. In either case, the outcome of measurement is quantitative description. Another useful way to distinguish or contrast measurement with assessment is to identify the essential purpose of assessment as informing while the purpose of measurement is clarifying. Thus, the special function of measurement tends to increase the sharpness or precision of the information provided. While efforts to clarify through quantification would seem to be a gain in the information gathering process, some argue that this increased precision is gained at the expense of qualities that cannot be represented numerically (Hesushius, 1991).

Assessment During Problem Solving

Consider the possible contributions of assessment to problem solving.

Documenting impressions. Psychologists have theorized for some time that thought directed toward problem solving originates from experiencing cognitive conflict (Berlyne, 1965; Festinger, 1957). This conflict occurs when a disparity exists between two important elements in our perception of the world. In schools, the conflict typically arises when a difference exists between what education personnel want students to do and what the personnel observe them doing. At such times the education professional thinks and behaves so as to reduce the discomfort produced by that conflict.

Because ordinary problem solving originates in these perceptions of difference between what we want and what we get, assessment can play a role in verifying or documenting the basis of our impressions. We can measure to increase the clarity regarding the perception of difference between our expectations and current reality. Initial impressions are certain to be implicit; therefore, assessment can help to make that experience explicit. For example, the feeling that student is having difficulty learning in school will be based on natural interactions and observations. That feeling can be objectified through collecting data on the student's current level of performance and contrasting it with our expectations for that performance. The current popularity of alternative approaches to assessment, particularly observation-based approaches, might be attributable to the fact that these more naturalistic methods of assessment authenticate the intuitive perceptions of the stakeholders who experience, observe, and develop impressions through their interactions with the students. Indeed, the term "authentic assessment," though prejudicial in its common usage, underscores the desires of many to document their sense of real student competence.

Clarifying and defining discrepancies. A distinction often not made explicitly in problem-solving models is that between sensing and defining. While sensation is an intuitive process, definition is formal and explicit. The distinction can be clearly understood in the difference between the statements "I think something's wrong" and "I wonder what it is." While the former statement is a reflection of the feeling of discomfort or cognitive conflict, the latter statement directs us to explicitly formulate the conditions producing this discomfort. In defining and clarifying problems school psychologists need to identify the discrepancies at the basis of the cognitive conflict. The discrepancies of particular interest to professionals involved in developing human performance are those between what students are doing and what the significant others in those student's environments would have them do.

Assessment for purposes of clarifying a discrepancy requires a school psychologist to collect information documenting both the current level of student performance and the level of expectation desired by those significant others who sense and perceive the existence of a problem. Useful assessment within this framework requires as much attention to assessing the standards for performance by those whose expectations contribute to the discrepancy (typically teachers or parents) as to collecting data on the current level of student performance. This will mean that diplomatic and sensitive probing of both the subjective and objective dimensions will have to be undertaken. Whereas objective assessment will involve establishing the desired characteristics of student performance in terms of frequency, magnitude, latency, or topography, subjective scaling will require obtaining an expression of the perceived importance of the discrepancy from the person who believes the problem exists.

To illustrate how assessment is conducted to clarify and document the existence of a problem consider the example of work completion. We could begin our assessment by collecting objective data on the percentage of current work being completed by that student and find she is completing between 60%

and 70%. We might then explore carefully with the teacher to determine what his standard is for work completion by students in his classroom and find that he expects 90% to 100% of the work to be completed. By collecting this information we have established a quantitative difference in performance of 30% between what the teacher wants and what the teacher is getting from this student. At this point, however, we do not know how important that difference is to the teacher. For some teachers a difference as small as 15% between what is desired and what is obtained is extremely important while for others a difference of 30% is viewed as only moderately important. This distinction between the magnitude of a problem and its perceived importance is the difference between quantification and values.

Generating alternatives. Conducting assessments for purposes of developing alternative solutions to a problem, while widely undertaken, is still an uncertain technology. Assessment of this type is typically termed "diagnostic" and is organized on the assumption that information from student performance directed toward interventions will be more effective than not collecting this information. The reality is, however, that over a decade ago Arter and Jenkins (1979) found scant empirical evidence supporting the effectiveness of differential diagnosis, and little evidence has developed since that time. The limitations of diagnostic assessment for generating interventions is not limited to more traditional differential diagnostic procedures using ability and personality tests. Current interests in describing the ecology of the classroom as a basis for developing interventions have not yielded rich results with respect to the differential effectiveness of interventions created from these ecological assessments over more traditional diagnostic prescriptive approaches. The same can be said for using currently popular efforts to assess "learning styles" and develop strategies consistent with those styles. Finally, while a subskill assessment approach makes sense to some, it has been widely criticized by others. At present it is perhaps best to expect relatively low cost-benefits ratios from the use of assessment to generate solutions to problems.

Documenting interventions. It may seem surprising to consider the role of assessment in documenting that interventions are occurring as intended. However, the experience of school-based researchers has established the importance of determining treatment "fidelity" when exploring treatment effects. Equally clear is the need to ensure that problem solution alternatives have been implemented and are operating with sufficient intensity before it is possible to evaluate their effects. Many of us have had the experience of working as a collaborative consultant to identify and plan what seemed to be a reasonable and potent intervention for solving a problem only to find upon subsequent review that the intervention was only partially or incompletely implemented. In such cases we may not have solved the problem as intended, neither have we established whether the problem could have been solved had the intervention been implemented. To actually test the effectiveness of solution alternatives, every effort must be made to document that the alternative has been fully and completely developed and that the student experiences that intervention. We can only wonder how many potentially successful solution alternatives have been discarded because the intervention was insufficiently implemented.

Formatively evaluating solutions. For some time a distinction has been made between formative and summative evaluation (Scriven, 1967). The evaluation of a program during its implementation is formative; while summative evaluation occurs upon completion of a program to determine whether it has achieved its goals. The purpose of formative evaluation is to determine the likely success of an intervention during its implementation so that it can be modified or changed to increase the likelihood that intended results will be achieved. This distinction is useful within a problem-solving framework because it clarifies that assessment should occur during implementation to inform decisions about program adjustment. In the Miller, Galanter and Pribram (1960) TOTE model described earlier, formative evaluation occurs when cycling through a test-operate-test-operate-test cycle until testing reveals that one can or should exit the situation. The advice, "If at first you don't succeed, try, try again" well captures the essence of both TOTE and the purpose of formative evaluation. Not surprisingly evidence exists that formative evaluation of interventions increases their success. Indeed an argument can be made that along with conducting assessment to initially clarify the nature of a problem, assessment as a basis for formative evaluation contributes most significantly to problem solution. For that reason considerable attention will be given in the remaining sections of this chapter to the school psychologist's role in formative evaluation of intervention attempts.

Determining success. Assessment contributes to problem definition in much the same way it contributes to determining whether problem solution has occurred. In evaluating program success the same assessment procedures that were used initially to clarify the discrepancy are used to establish whether that discrepancy has now been eliminated. To do this requires the same degree of thoroughness in determining both the degree and importance of any difference between what is desired and what is actually occurring. Following from our earlier example of work completion, this means that we must once again determine the difference in percentage between the student's current level of work completion and the level specified by the teacher. In addition, the teacher's perception of the importance of that difference must be reassessed. In the best of all worlds no difference will exist. In reality, we may find that while the student's level of work completion has increased, the teacher's standards or his values regarding the importance of a difference may have changed. Although we may view this as negative in our efforts to solve the problem, evidence exists that "goal ambitiousness" and goal raising by teachers are important factors in increasing the level of achievement attained by students (Fuchs, Fuchs, & Deno, 1985). Indeed, the purpose of school psychology presented at the outset of this chapter was continuous solving of human development problems. While the TOTE model provides for exiting a problem when the test reveals that the problem has been solved, both our ambitiousness and that of the teacher's to optimize development should mean that exiting is a momentary vacation from work rather than a condition of our employment.

Solving the Problems Called Handicaps

In ideal circumstances school psychologists are free to act on the complete range of developmental problems encompassed by schools. In reality, however, most school psychologists are constrained to give priority to that set of problems called "handicaps." In this section the meaning of the term handicap is explicated by contrast with the related terms "disability" and "impairment."

Disabilities and handicaps. In 1976, Public Law 94-142 was passed as the Education of the Handicapped Act (EHA). When the revision of that law was passed almost 15 years later as PL 101-476, it did so as the Individuals with Disabilities Act (IDEA). The change from using the term "handicap" to the term "disability" occurred not only in the title, but also throughout the text. While it would be easy to assume that this was simply a cosmetic change having more to do with a shift in popular usage than with substance, people with disabilities and their advocates to not operate from that assumption. Indeed, people with disabilities see as central to their concerns the need for society to clearly understand the distinction between the concepts represented by the terms handicap and disability. What is this distinction?

Handicaps are problems. Thus, handicaps are a difference between what someone does (or can do) in a particular situation, and what is required for the person to be successful in meeting the demands of that situation. If a person can move about in the environment within a wheelchair, but to gain access to a building is required to climb a stairway, then a handicap exists. Similarly, if a person has low visual acuity but must see words projected on a screen or written on a chalkboard in order to take notes in a class, then the person is handicapped. A student in high school who cannot read a textbook well enough to complete the daily work assignments is handicapped. We can see in each of these examples that a discrepancy exists between what the individual can do and the task demands necessary for success in that situation.

Whereas handicaps are conditions defined by the relationship between what the individual can do and must do to succeed at a particular task, disabilities are conditions of the individual. In each of the examples just provided, the disability is defined by what the individual's level of performance is in that situation. Thus, difficulty or inability at performing to a level typical for that individual's peers defines the individual's disability. Disabilities, then, are defined by the normative differences in ability while handicaps are defined by the minimum standards for successful task completion in a particular situation.

Another important distinction between disabilities and handicaps is the degree to which the existence of the condition can be altered by changing the environment. In the foregoing examples, the existence of each handicap can be altered by changing the task demands. If wheelchair access to a building is created, the handicap no longer exists. If large print paper copy is provided at the student's desk, the notetaking handicap no longer exists. If the information required to complete daily work assignments is made available through audio tapes, then no reading handicap exists. While in these examples the handicap can be eliminated by altering the task demands, the same cannot be said for individual disabilities. In each instance, the individual's level of performance in walking, seeing, and reading is unaltered by the modifications made in the requirements for success. Normatively defined disabilities change only when the individual's performance changes or the norm group changes.

The role that norms have played in defining disabilities has been clear for quite some time. What has been less clear is the role that society plays in creating the handicapping condition. Even in acting as a caring society we have tended to view handicaps as problems possessed by the individual that we might try to help them to cope with or overcome. In changing the language of the law from handicap to disability, advocates for people with disabilities were trying to influence us to think more completely and carefully about our role and responsibility when we create the requirements for task success and then assume that those who do not succeed bear the full responsibility for their lack of success. They have tried to emphasize that handicapping conditions are created at least as much by society as they are by the level of an individual's competence.

The handicapping conditions created by the schools are many and not easily identified. When a student struggling to read connected discourse is required to do extensive reading in order to earn an "A" or a "B" in the classroom, a handicapping condition exists. The student may possess a reading disability but is not handicapped until required to use a level of reading beyond his or her current skill in order to be successful in the classroom. The same exists for a student who does not write well or compute fluently. If standards of success or conditions of performance are established that exceed the student's current level, then a handicapping condition is created. Thus, students who have difficulty learning a range of communication skills in the school might be viewed as learning disabled; however, their disability in learning school tasks will not be a handicap until certain standards of performance are imposed as requisite for them to be successful in the classroom.

The third concept related to disability and handicap is "impairment." Impairment is a term used in reference to dysfunction in a biological process or structure. Impairments may, or may not, be related to the level of an individual's ability or performance. Spinal nerve damage is an impairment that can affect the level of an individual's ability to move the lower extremities for purposes of ambulation. Similarly, damage to the optic nerve or the retina may be a biological condition underlying or affecting visual perception, and damage to auditory mechanisms may result in lowering an individual's ability to discriminate speech sounds. Historically, we as a society have written laws assuming that disabilities in performance were caused by specific and identifiable impairments, and strong arguments are made that all disability conditions funded under federal law should be clearly based in biological anomaly. This line of reasoning has proved particularly problematic for conditions such as learning disability, emotional disturbance, and mild mental disabilities where impairments are difficult to identify. Current research to map the brains of people who are "dyslexic" using advanced electronic techniques such as PEP scans and magnetic resonance imaging are viewed as useful not only because they may someday lead to the development of appropriate treatments, but also because an impairment justifying special education resource expenditures may be identified in the brains of individuals who have difficulty learning to read.

While fairly clear connections can be drawn between some biological conditions and specific levels of competence, the relationship between the biological condition and the level of functional performance obtained by the individual is typically not direct and is always very complex. When central nervous system trauma occurs through closed head brain injury or spinal cord injuries, the degree to which an individual will lose or recover functioning associated with those injuries is difficult to predict. While this is due in part to difficulty in estimating the degree of healing or damage, it is also due to the fact that the central nervous system is able to adapt in ways that produce improved functioning even when impairments exist. Considerable evidence exists that, when the dominant cerebral hemisphere is traumatized, the less dominant hemisphere will take over some of the functions normally associated with the dominant hemisphere. The same difficulty exists when attempting to estimate the performance consequences of sensory impairments. Audiometric and opthomological examinations cannot ascertain the degree of useful hearing or vision. Legal classifications of blindness based solely on sensory acuity often result in the apparently contradictory situation where someone who is "blind" can read ordinary print. Further, while some students classified as hard-of-hearing can complete their schooling without the use of technological aids or compensatory programs, others have such great difficulty developing oral language skills that they seem more likely to succeed in a residential school where the culture is based in American Sign Language.

In summary, disabilities are conditions of the individual referring to the fact that their level of competence, performance, or ability to do something is consistently and significantly lower than that of their peers. Impairments are biological conditions thought to underlie an individual's seemingly unalterable disability status. Handicaps are conditions that exist when successful functioning in an environment requires a level of ability beyond that possessed by the person. A neat, simplistic formulation of the relationship among these three terms is that biological impairments produce disabilities that often result in the existence of handicaps. While relatively simple and straightforward examples of this formulation might exist, the functional relationships among these three terms are typically very difficult to establish.

Severity of disability. No discussion of disabilities and handicaps is complete without consideration of the degree or severity of these conditions. Earlier in this chapter, the magnitude of a problem to be solved was described as having two parameters: its measured or objective dimension and its reported or expressed values dimension. The same two parameters apply to the concepts, disability and handicap. The objective or measured severity of a disability refers to the scaled difference between the individual's performance on a particular task and the typical performance of the peer group. If presented with text passages from the local newspaper and asked to read them aloud, students will vary in the number of words each reads correctly and incorrectly in a fixed period of time. The result is a dimension of performance from relatively lower to higher levels of accuracy per unit of time. The difference in individual performance on this particular task, then, is an objective measure of their ability to read aloud from connected discourse. Whether performance on this task is considered "disabled," however, will depend upon the application of another person's standards of performance. Performance standards are external to the task itself. The number of words read correctly and incorrectly is simply a fact about performance until a framework for interpretation is created. The most common standards for interpretation applied to human performance, of course, are normative. Informal normative standards are usually acquired by teachers in their work with students. These informal standards account for students being viewed as "able" on a task if they perform similarly to students of comparable age and exceptional if they perform much better or worse.

Norms provide a useful basis for objectively discriminating between levels of performance and thereby help to establish degrees of ability and disability. Yet it should be kept in mind that the value of performance on a particular task is not inherent in the fact that people perform differently on the task. The value of performance on the task derives from the need for competence on that task, especially within a social context. For example, being able to read words with the same speed and accuracy as one's peers only becomes important when the personal and social consequences of performance on that task are important. Thus, performing more than two standard deviations below the mean at "singing in tune" may be objectively quantifiable; however, it will not be identified as a severe disability. The same cannot be said for similarly low performance in reading and writing.

Severity of handicap. Like the severity of disabilities, the severity of handicaps is defined both objectively and subjectively. The measurable and the expressed values dimensions of handicaps are not identical to those of disabilities, however, The performance aspect of a handicap may be measured in the same way as a disability; however, the standard for successful performance may be established quite differently. Recalling that disabilities are most often defined on the basis of performance relative to norms, the performance standards or requirements denoting the existence of a handicap may be established independently from current norms.

This distinction is well illustrated in the current national furor over the performance of American students in math and science. Using normative standards to evaluate the performance of U.S. students indicates that nearly 85% of the students perform normally (i.e., at a level equal to, or greater than, one standard deviation below the mean). Although 85% may seem satisfactory to some, U.S. policy makers find this current level of performance insufficient and want it raised so that our students are performing better than the students from all other nations of the world by the year 2000. The basis for establishing these year-2000 standards may not be clearly evident, but they do indicate certain assumptions about what is both possible and desirable for students in American society. Because it has not yet been established whether it is possible to attain the desired level of performance, it can be assumed that such a goal is both nonempirical and nonnormative in its origins. More common examples of how nonnormative standards are imposed to create handicapping conditions can be found in the examples of parenting. A parent may establish that a son or daughter must attain a particular grade-point average to drive the car. The son or daughter may already be performing "normally," but the parent may desire or value a higher standard of academic success. This standard is established out of the values of the parent without particular reference to normative grades. These examples illustrate that while disabilities are defined by normative standards, handicaps are defined by somewhat more arbitrarily established standards.

Consequences and handicaps. Handicaps are also distinguished from disabilities by the fact that an incentive condition is contingent upon performing at the requisite level. In the parenting example just given, if the parent establishes a grade criterion that exceeds the student's capability, then failure results in the loss of an important incentive for the student. In the earlier illustration of handicap, employability within a building depended upon access to the building by a person in a wheelchair. Thus, not only does loss of access to the building occur when the environmental conditions are beyond the individual's level of performance, but also the loss of rewards associated with employment in that building. Those low-performing readers described earlier who cannot read their subject-matter texts well enough to do their daily work are not only disabled but handicapped. This is so not simply because the requisite performance standards exceed their current capability, but also because in failing to attain those standards they will not achieve the desired grade outcomes. The severity of a handicap, then, is based both on the magnitude of the discrepancy between what the individual can do and what the task requires and the loss of an important incentive associated with inadequate performance.

Relationship of handicaps to problem solving. It should be clear from the foregoing discussions that the definition of "handicap" parallels the definition of "problem" developed at the outset. Problems are defined as the difference between the performance wanted in a particular situation and the actual performance gotten in that situation. Handicaps are a particular type of problem where environmental demands are created that exceed a person's current level of capability and then the individual is expected to meet those demands in order to receive a valued incentive. In ordinary cases these handicaps are created by imposing what are considered to be conventional standards for performance on individuals disabled in that area of performance. The problems called handicaps, then, must be solved by reducing the difference between disabled performance and the standards of performance required for success.

BEST PRACTICES

Identifying and Defining the Problem

As with problem solving in general, solving the problems called handicaps requires cycling through the process of identification and definition, exploration and implementation of alternative solutions, and evaluation of the effects.

The key to success. Perhaps the most significant contribution to be made by school psychologists to solving handicap problems is made through collaboration with others who are invested in the problem to clearly and explicitly define the problem to be solved. This contribution requires skill in working sensitively with those who have created environmental demands exceeding the individual's capabilities both to make explicit and establish the necessity of those standards. As noted earlier, clarity and precision in problem identification and definition are essential to successful problem solving. School psychologists are (or should be) uniquely capable of contributing to increasing clarity and precision through the application of their knowledge of assessment procedures, especially the alternative assessment procedures described earlier in this chapter. To significantly contribute to problem solution, school psychologists must be able to develop and select assessment procedures that aid in precisely defining both the individual's current level of ability and the environmental demands in excess of that ability.

As school psychologists collaborate with others invested in the handicap to use assessment procedures to clarify the existing discrepancy they must be particularly sensitive to the values at the heart of the performance requirements. They must be mindful that no assessment procedure alone is sufficient to establish the existence of a handicap. They must emphasize that, at best, scores from standardized tests reveal the performance differences that aid in defining disabilities rather than handicaps. They do not establish that a problem exists that must be solved. Differences within the norm group on a particular test are meaningless until the values context associated with the performance on that test are clearly explicated and agreed upon. As stated later in this chapter, this issue also becomes important in attempting to establish both the need for special education and the annual goals for an Individualized Education Program (IEP).

Cultural imperatives. When attempting to collaborate with others in examining the value context surrounding handicaps, the school psychologist may find the idea of cultural imperatives useful in identifying those performance discrepancies important enough to be referred to as handicaps and those that are not. The term "cultural imperative" refers to those types of competence so highly valued by a society that resources will be allocated to overcome developmental discrepancies in those areas. In the U.S., for example, considerable resources are allocated to support learning to read, write, and compute. The high priority placed on competence in these domains is easy to infer simply by examining both the daily schedule of lessons and the curriculum of the schools. Not only do the learning activities occupy "prime time" in the school day, but when students have difficulty in learning these tasks, additional resources are used to develop remedial and compensatory programs in an effort to overcome students' failure to develop essential competence in literacy and numeracy. Further, both federal and state policy initiatives have been created to ensure that American students excel in these areas.

Cultural imperatives are easily understood when contrasted with cultural electives. Cultural electives are those abilities that, while valued by society, are given lower priority for resources than cultural imperatives. Musical abilities are good examples of cultural electives. Students are often given the opportunity in school to develop some degree of competence in music; however, relatively small amounts of time in the schedule are provided and, when resources are short, these activities are among the first to be cut from the school curriculum. Indeed, while someone may be described as not musically inclined, it is unlikely that the individual would be referred to "musically disabled." While a performance discrepancy may be as large in music as it is in reading, no additional societal resources will be forthcoming to overcome that discrepancy. Clearly, it is the difference in value ascribed to these activities within the culture that established that one disability is important and the other is not.

Situational handicaps and chronic disabilities. A second set of concepts useful in making problem-selection decisions is the distinction between situational handicaps and chronic disabilities. It follows from earlier discussion that handicaps can be created in any situation and may exist for only a moment in time. That is because handicaps typically are created by society's members making performance demands that some individuals cannot meet. As pointed out earlier, handicaps can be created for people whose abilities are quite typical. Distinct from situational handicaps, chronic disabilities are trans-situational and enduring. An otherwise typical student, or group of students, can have great difficulty meeting the performance demands of a teacher because the teacher has not made work demands appropriate to their level of skill. This problem is quite different from the one where a student has had serious difficulty in learning to read for several years regardless of the teacher and is routinely handicapped in school. In the former case the handicap is situational, while in the latter case the disability is chronic. In both cases discrepancies exist between what the individual can do and must do in order to succeed, but in the case of situational handicaps the problems are relatively temporary or local. Students with chronic disabilities must routinely endure the consequences of failing to meet sociocultural demands.

While this distinction between situational handicaps and chronic disabilities may seem an obvious one, it is mentioned here to preempt questions regarding the priority that must be given to different discrepancies when selecting problems. Ultimately, the value system that underlies resource allocation and the rules related to those values will determine the priority among problems to be solved. As will be discussed later, however, the funding provided for solving special education problems is intended to assist those people whose disabilities are chronic rather than those with situational handicaps. This means that school psychologists must be able to develop assessment procedures that can aid in distinguishing between situational problems and those that define the individual as disabled. As before, norms are useful tools in making this judgment because they emphasize individual differences in ability rather than failure to meet societal standards.

Problems as relational. A point often overlooked when using the discrepancy model in defining and selecting problems is that problems are not possessed by the individual. Problems are defined by the relationship between an individual's performance and the performance level that must be attained in order for the individual to be viewed as successful. Nor does the problem reside in the standard or desired level of performance. Rather, using the discrepancy model clarifies that the problem is relational — residing in the difference between what the individual does and what must be done. A problem may well exist when a student's reading skill is insufficient to accurately complete daily work assignments. To attribute the problem to the student's lack of reading skill or to the standards of performance set by the teacher is neither necessary nor helpful in problem identification and definition. Sensitivity to this issue helps to avoid the problem of "blaming the victim."

Problem ownership. While defining problems relationally helps to avoid fixing blame by identifying what *is* the problem, it is useful to identify who *owns* the problem. Ownership of a problem is determined by identifying those individuals who view a performance discrepancy as being important and are initiating action to solve the problem. These individuals may indeed not be those who established the performance requirements that the student cannot meet but rather are concerned that a discrepancy exists. For example, classroom teachers may be relatively unconcerned that some students cannot do daily assignments accurately — believing that low ability makes this inevitable. Likewise, students may come to accept their failure as a part of life. Parents, however, may be deeply concerned and may press the school for adaptations in their children's program. In such cases neither the parents' performance nor their standards define the problem, but they are the owners of the problem. To paraphrase a well-known expression, "problems are in the eye of the beholder." Once this is understood, it becomes clear that it is the owners of the problem whose desires and concerns must be made explicit to clearly identify and define a discrepancy and to establish its importance. Practically speaking, teachers and parents own most common school problems. They are the ones most often expressing concern and taking action. Although it is tempting to identify the students as owning the problems, this is typically not the case.

Defining discrepancies quantitatively. When a teacher expresses concern over a student's performance, the language used often represents the difference between what the student is doing and what the teacher expects the student to do in qualitatively different terms. Thus, for example, a teacher might say that a student is having "difficulty in reading" and, when asked for more details, that the student is "unable to complete his independent work accurately." In attempting to clarify this problem, the school psychologist is confronted with the fact that the teacher's initial statement implies that the student has a skill deficiency in reading, while the second statement points to a different type of performance — "doing work accurately." While discrepancies may exist both in reading skill and work completion and while failure to complete work accurately may be due to reading difficulty, assessment of a difference between what the teacher wants and what the student does requires scaling performance along the same dimension. Thus, the student's "reading difficulty" needs to be operationalized and the teacher's expectations need to be expressed in the language of that operationalization. For example, careful probing may yield specific information regarding the reading book or books used for instruction and the level of reading skill necessary to be considered performing acceptably in those reading materials. It may be ascertained that the teacher expects the student to be able to read from a fourth-grade literature book at approximately the same rate and accuracy as the average student in the class. The quantitative difference between the teacher's performance expectation and the student's actual performance in fourth-grade literature could then be obtained by comparing the student's performance to a normative sample of the class. The difference in the number of words read correctly and incorrectly by the peer sample and the target student could be used to represent a reading discrepancy along the same quantitative dimension. If the teacher wished to focus instead on work completion, then the same general approach could be used to scale performance difference in work completion along the same dimension.

Skill development problems, by definition, are discrepancies where the teacher's performance expectations exceed the student's level of performance. At the same time, this does not mean that the discrepancy always is one where the student's performance is lower than the performance that the teacher desires. Behaviors deemed inappropriate or incorrect often occur at a level higher than that desired by the teacher. These "intrusive" behaviors include such things as high error rates in reading, spelling, and computing. They also include high levels of social behaviors like hitting, making noise, or being out of an assigned place. Whether the performance discrepancy is one where the actual performance is perceived to be too high or too low relative to the teacher's standards will not alter the basic utility of defining the problem in terms of quantitative rather than qualitative difference.

In closing this discussion of problem identification and definition, it is useful once more to emphasize that the key to successful problem solving is careful identification and definition of the problem. In mobilizing problem solving, resources move to the specified problem. Inaccurate or inappropriate problem selection will mean that the resources will be focused on the wrong problem. Unfortunately, it is all too common to find after implementing a problem solution that the owner of the problem expresses dissatisfaction with the results not because the intervention plan has failed, but because it has been focused on the wrong problem. School psychologists must be careful not to limit teachers to defining discrepancies in the preferred terms of psychology. Defining a reading problem in terms of the difference between the speed and accuracy of a student reading from fourth-grade literature in contrast to a normative sample of that student's peers may be preferred by school psychologists. Yet this approach to assessment may miss completely the problem felt most strongly by the teacher, that is, the discrepancy between the work completion rates of the student and the teacher's desired level of work completion. The school psychologist may be more interested in focusing on reading skill problems when the teacher is more interested in developing good work habits. In such a case, a problem might be solved but not the one the teacher wanted.

Developing and Selecting Alternative Solutions

Once problems have been carefully defined, it is possible to proceed with generating alternative plausible solutions to reduce the discrepancy. Because most school-based performance problems involve skill discrepancies it is common to assume that a problem is best solved by changing student performance to conform to the implicit or explicit standards from which they differ. While improving development is the goal of school programs, it should be remembered that problems can also be solved by adjusting performance requirements to be congruent with individual student capability. Of course, particularly in the case of those problems called handicaps, changing performance is always more difficult than altering the environmental conditions necessary for success.

Discussions of whether to seek problem solution through changing performance or adjusting requirements are fraught with potential controversy and must be handled carefully. In most instances this will mean that the owners of the problem must become engaged in a constructive discussion of the benefits and costs likely to be incurred through modifying the performance or the environmental demands. Central to the developing and selecting of problem-solution alternatives should be the idea that discrepancies can be reduced by altering the performance, the task requirements, or both. Within the problem-solving framework provided here, a problem is eliminated when the owner no longer identifies an important discrepancy. Adjusting task demands to meet current student capabilities or moving performance standards to be congruent with current levels of performance result in problem solution. While the problem is solved for the previous "owner," however, the school psychologist continues to bear a moral obligation to consider the long-term consequences of that type of solution for the student.

Diagnosis: An undeveloped technology. Often, instead of adjusting task demands, those involved decide that the problem is better solved through an intervention designed to improve student performance. When this occurs it is important to remember that, in the language of cognitive psychology, problems are "situated" — that is, they are defined by the specific circumstances in which they exist. And because problems are situated, their solutions also are situated. Therefore, success in problem solving rises with increases in specific knowledge of the individual and the circumstances. To obtain this greater knowledge regarding the nature and circumstances of a problem, school psychologists often conduct testing for the purpose of diagnosis. The intended outcome of diagnostic testing, of course, is an interpretation of assessment data that provides a plausible explanation for the student's performance. In the case of chronic disabilities, the diagnostic question focuses on why students are performing at a level significantly lower than their age norms.

Despite the widespread use of diagnostic procedures, it is important to realize that in most cases problems are so specifically situated that it renders useful diagnosis virtually impossible. The problem of situation specificity in diagnosis may well be why a reliable and valid technology of differential diagnosis and prescriptive treatment is, as yet, unavailable (Snow, 1989). Unfortunately, a popular literature exists that learning problems can be overcome through greater attention to individual differences in "learning styles" (Snider, 1992), and school psychologists are too often cajoled into "going beyond the data" when meeting with others to solve problems.

Problem solving as experimenting. Twenty-five years ago Donald Campbell advised us in his presidential address to the American Psychological Association to treat "Reforms as Experiments" (1969). His thesis was that new or modified programs should be viewed as experiments that require systematic evaluation, because the outcomes of those new or renewed programs were always unpredictable. In general, then, people introducing changes in programs at any level should vigorously advocate for collecting data in such a manner that the effects of program changes can be determined. In taking such an experimental approach, decision makers can avoid being "trapped" into the position that the changes for which they are advocating are certain to be effective.

Those working to solve educational problems, at any level, would be well advised to take the position advocated by Campbell. Psychological knowledge at best can only be used to estimate probabilities. Like the National Safety Council's predictions regarding the number of people who will be fatally injured in auto accidents during a holiday weekend, generalizations about the effectiveness of education programs are more accurate for groups than they are for individuals. An intervention strategy with a 50% success rate in influencing student behavior may help increase the chance of selecting a successful strategy, but there is no certainty that the intervention will be effective in solving a particular problem. In their efforts to intervene in school programs, school psychologists are the decision makers who should avoid being "trapped" into acting as if they are sure that a particular intervention will solve a specific problem. Instead, all involved should be encouraged to view the proposed solutions as operational hypotheses that can be empirically tested. This approach encourages the development of assessment procedures that are problem specific and produce data that help evaluate the problem-solving efforts.

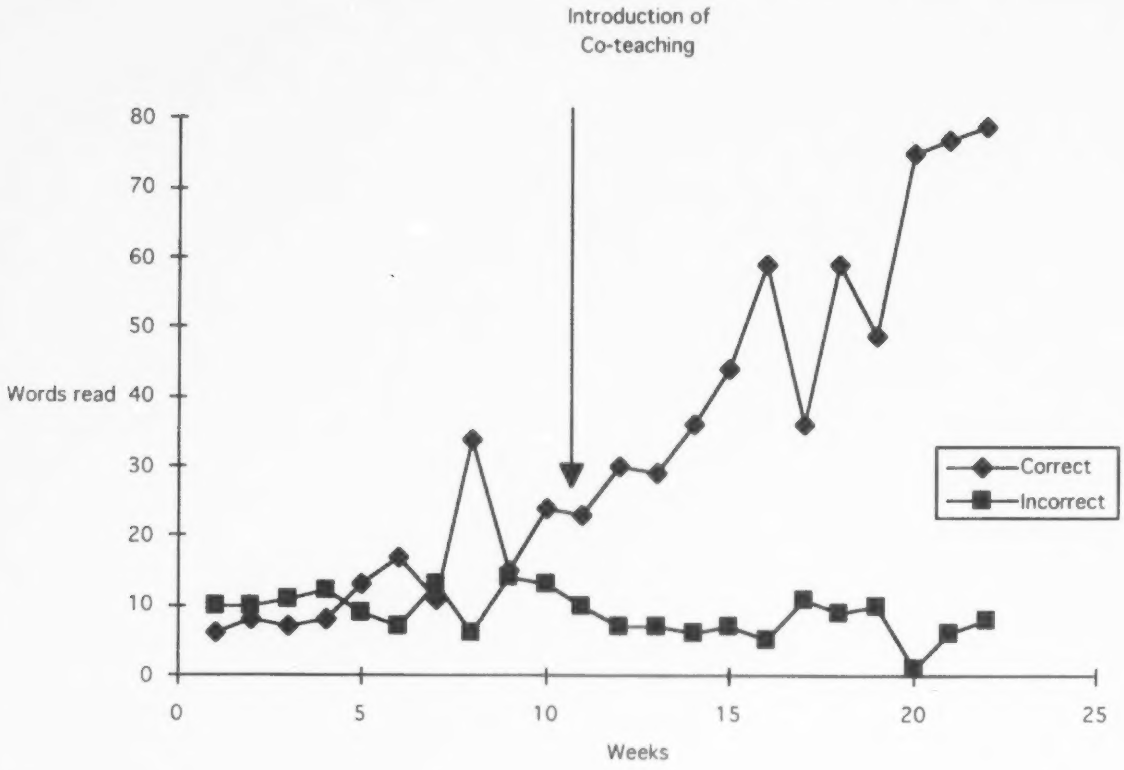
Progress Evaluation

When approaching interventions into student programs as experiments, a critical issue arises concerning the method to be used for empirically testing the effects of those interventions. The most common method used in education to evaluate programs is an arrangement where students are pretested prior to implementing a program change and then posttested at program completion. Pretesting is used to create a "snapshot" picture of the initial difference between actual and expected performance, and posttesting provides a similar static picture at the completion of an intervention that aids in determining whether the discrepancy still exists. While a pre-post test arrangement makes an important contribution to evaluating problem-solving efforts, it actually constitutes a weak set of conditions for making valid judgments about the effectiveness of interventions (Campbell & Stanley, 1963). Recent developments in procedures that can be used for monitoring individual student progress now provide an alternative to pre-post testing arrangements.

Progress monitoring. In general, procedures for individual progress monitoring are based on direct and frequent observation of performance on the tasks or in the situations representing the essential outcome of the intervention. Within this approach, performance assessment occurs before, during, and at the end of interventions. This produces a series of data points across time that not only permits the usual estimate of current performance level, but also estimates of both trend and individual variability. Estimates of trend and variability prior to program reform are derived from repeated measurements to establish a baseline for these characteristics. Trend and variability in individual baseline performance are then combined with initial level to create a stronger database for testing intervention effects. Evidence exists that, when individual progress monitoring is used in a formative evaluation design, intervention effectiveness can be increased (Fuchs & Fuchs, 1986). The most probable explanation for this increased intervention success when progress monitoring occurs is that the empirical records of intervention effects are continuously available for use in deciding whether a program is producing intended effects and should be continued, or is ineffective and should be modified or abandoned.

An illustration of how individual progress monitoring can serve as an aid to testing successive intervention attempts is presented in Figure 1. As can be seen in the figure, the progress monitoring data reveal that initial efforts to improve the student's reading performance were relatively unsuccessful and that an alternative approach to teaching the student to read was needed. After a series of trials, a collaborative program involving direct instruction was created and the trend in the student's reading performance shifted upward. Such a graphic record is important because it clarifies many things for decision makers. First, it clearly represents the difference between the student's initial level of performance and the standard of performance desired by the teacher. Second, by projecting the trend from the student's baseline performance to the goal date at the end of the graph it is possible to estimate the magnitude of the difference that would obtain on the goal date if no program reform occurred. Third, when the rate of growth in per-

FIGURE 1.



formance required to attain the desired level on the goal date is drawn on the graph it provides continuous feedback on progress toward the goal. Finally, the degree of program improvement produced by each successive reform can be estimated by contrasting the performance trends produced during successive reforms. This more dynamic picture of performance in relation to changes in student programs, then, creates a richer database for formatively evaluating program reforms than is available through pre- and posttesting of individual student performance.

Progress indicators. As with any effort to base decisions on measures of performance, successful use of individual progress monitoring necessitates that the data used for decision making validly represent the problems and goals of program intervention. Unfortunately, despite widespread interest in assessing educational outcomes, little agreement exists regarding which data are reliable and valid indicators of the culturally imperative outcomes of schooling. In the absence of a research basis for indicator selection, "authenticity" (Wiggins, 1993) and "social validity" (Wolf, 197) are currently the most highly touted characteristics of data on program outcomes. While these characteristics are not well defined, the essence of authenticity seems to be that individual performance on tasks that are "real" and "meaningful" be observed as a basis for appraising competence. While this concept is laudable in the abstract, efforts to operationalize authenticity encounter both technical and logistical problems. Nevertheless, good reasons exist to consider the authenticity of the tasks used to appraise performance. Perhaps authenticity can be partly ensured through establishing social validity, that is, the degree to which significant others in the individual's environment agree that the data to be collected represent the important treatment goals.

When authenticity and social validity are used as criteria for evaluating the use of standardized achievement tests, it is easy to see why they have been subject to so much criticism. A standardized reading achievement test, for example, might include a variety of paper-and-pencil tasks such as recognizing isolated words, selecting definitions of words, and selecting multiple choice responses based on the content of short segments of text. While ample psychometric evidence may exist for the reliability and validity of the data produced through measuring student performance on such tasks, such tests are criticized on the grounds that the tasks are not authentic in that they are not what people do when reading. An argument can be developed that a more authentic reading task involves sharing or communicating reactions or feelings in regards to the content of a story. If so, then assessment should be structured around the social and communicative aspects of the reading experience rather than around arbitrarily selected words and questions from text not selected by students out of their own interests.

In contrast to authenticity, determining the social validity of such a standardized test is based on the values of those invested in student performance. If they are less interested in scores on such a test than whether the students are using their reading skills to successfully complete relevant school assignments, then, the socially valid information would be student performance on school assignments rather than their scores on the standardized test. At the same time, because social validity is based on shared values rather than independent judgments of authenticity, it would be possible for performance on such a standardized test to be judged as socially valid but inauthentic.

Another important set of characteristics with respect to useful progress indicators relates to practical and logistical concerns. If frequent measurement of progress is useful to ascertain intervention effects, then assessment procedures must be efficient and economical. That is one reason why the administration of commercially developed achievement tests cannot be used in progress monitoring. Frequent monitoring also necessitates that multiple equivalent forms be used so that practice effects on the test itself do not accrue. Thus far, direct observation and recording of relatively brief performance samples embedded within the context of ongoing classroom activities has proved to be the most practical and logistically feasible solution to these problems.

SUMMARY

Evidence has accumulated that program reforms are more successful when systematic data-decision rules have been used to make program improvement decisions (Fuchs & Fuchs, 1986). The research in this area seems to reveal that people will collect data on the existence of a problem and then monitor progress toward goals, but they tend not to use the data to make timely changes in unsuccessful interventions. Indeed, this failure to modify programs in response to performance data has been identified by supervisors as the primary barrier to effective system-level implementation of progress monitoring systems in special education programs (Yell, Deno, & Marston, 1992). At least two approaches to overcoming this barrier are available and may be effective. The first solution is based on the use of computer technology to provide more direction when using the data to modify student programs. In this approach a structure is created for determining when and how a program might be modified to increase the likelihood of it success. Evidence has been produced revealing that the use of such a technology does, indeed, result in more effective programs (Fuchs, Fuchs, Hamlett, & Ferguson, 1992).

The second solution is to devote greater resources to developing and supporting professional practices consistent with effective use of progress-monitoring data to solve problems. This will require preservice and in-service training and accountability systems that encourage effective use of progress monitoring to formatively evaluate efforts to solve problems. As a relatively new practice, a data-based approach to problem solving must evolve as part of the natural practice of school psychology. As with any evolutionary outcome, the behaviors that become the "best practices" of school psychology will be determined by the degree to which those practices are adaptive for school psychologists. If survival in the culture of the schools requires the effective use of data-based problem solving, school psychologists must successfully adapt to that culture by learning and using effective data-based problem-solving procedures. System developers and managers must look to themselves if they want to identify the source of motivation for best practice.

In recent years, the trend in school psychology service delivery has shifted strongly toward providing intervention services to children, families, and schools. This direction is reflected in policy statements by professional organizations (e.g., National Association of School Psychologists & National Coalition of Advocates for Students, 1985; National School Psychology Inservice Training Network, 1985) as well as in major professional publications (e.g., Graden, Zins, & Curtis, 1988; Stoner, Shinn, & Walker, 1991). It is becoming increasingly possible for school psychologists to break out of the gate-keeper-for-special-education role and provide services with documentable benefits to students and teachers. With this shift has come the challenge and responsibility for school psychologists to expand the traditional role of disability-centered service delivery and move to an intervention and outcome-centered service delivery model.

OVERVIEW

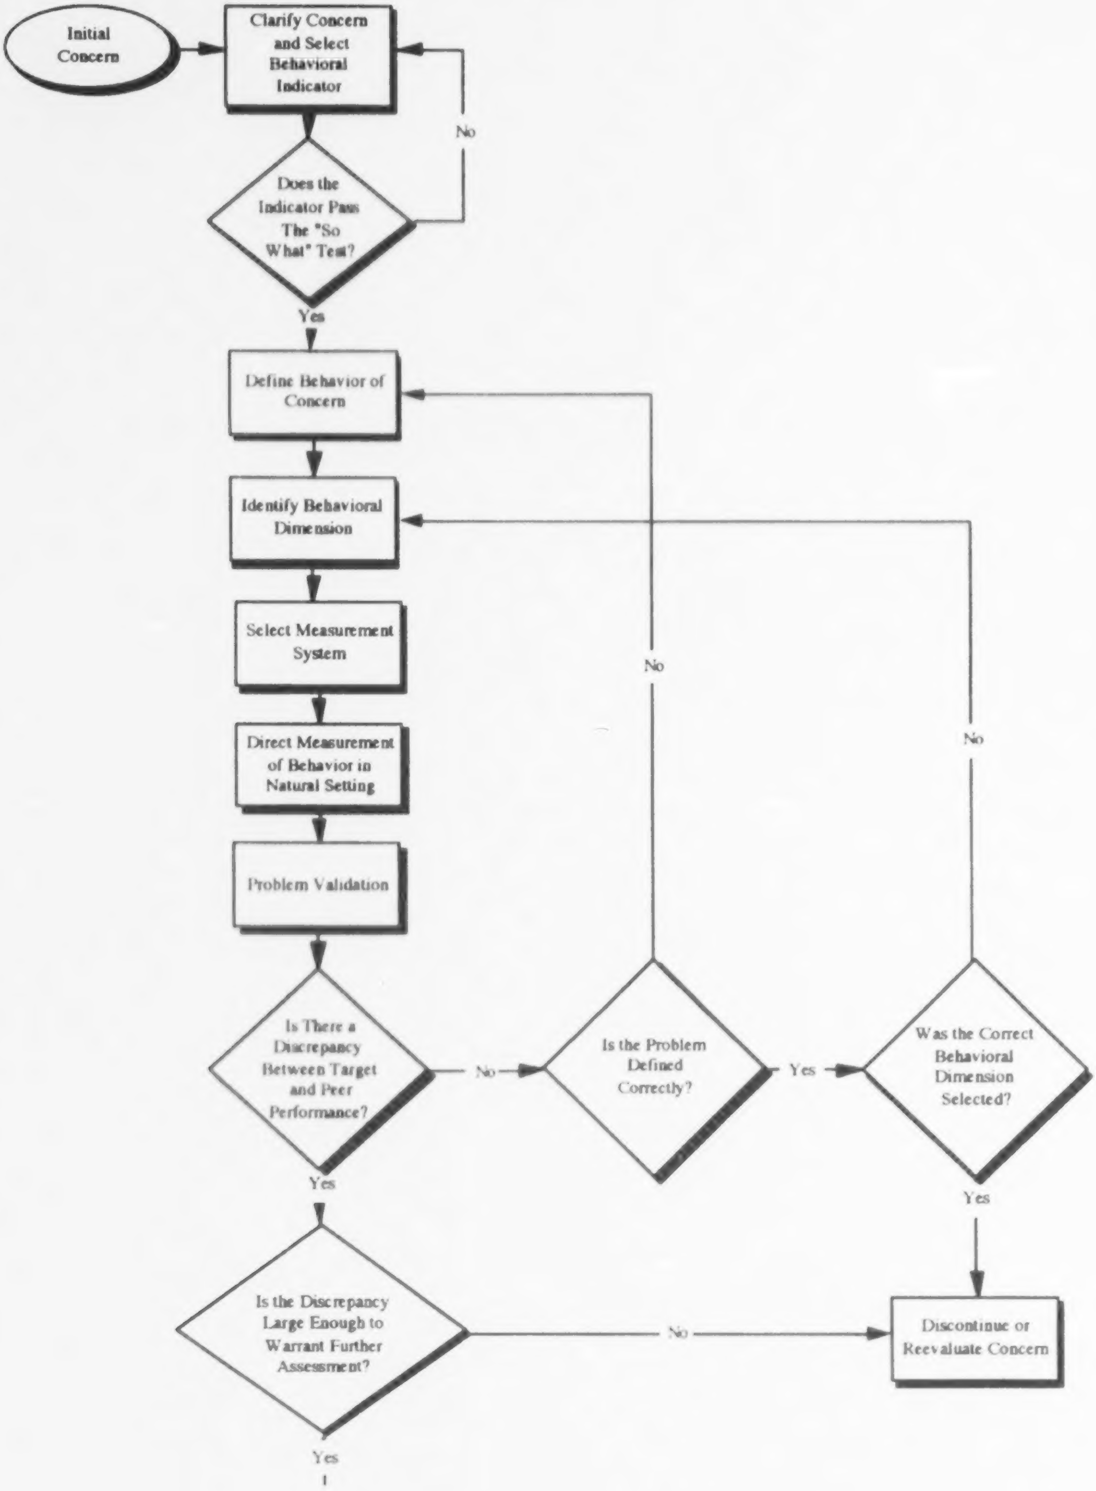
The purpose of this chapter is twofold. First, the concept *intervention* will be defined and a structure for implementing educational interventions will be presented. Second, critical components of educational interventions will be discussed and a format for documenting these procedures will be described. Space limitations preclude a comprehensive treatment of each quality indicator of interventions. Many of the quality indicators could and do have complete chapters or books written on them elsewhere. Hence, this chapter will provide a brief discussion of each indicator, provide references to more complete sources for each indicator, and illustrate how the indicators work together within a problem-solving structure.

What Is an Intervention

In reviewing the literature on problem solving and intervention design for this chapter, the authors noted an elementary but important omission in much of the literature regarding educational interventions. Many of the studies and book chapters focusing on specific educational treatments or interventions do not define what is meant by the term intervention, nor do they describe a structure in which the intervention will be carried out and evaluated. Translating these practices into positive student outcomes is problematic because it assumes that (a) educators share a common definition of "intervention" and (b) a structure for implementing interventions in schools is present. In educational practice, our experience is that these may be unfounded assumptions.

For the sake of this chapter, the term "intervention" is defined as a *planned modification of the environment made for the purpose of altering behavior in a prespecified way.* Three components in this definition are critical. First, interventions are *planful* in that the procedures to be applied are specified clearly and completely. Often they are documented in writing using a plan that communicates clearly the intent and content of the program. Second, interventions are *environmentally focused* in that the actions taken modify the environment, not the individual. For example, a reading intervention might involve changing a student's reading curriculum or instructional arrangements for the purpose of improving his or her rate of skill acquisition. In this case, the goal is to improve individual performance, but the focus of teacher action is on the environment, not on the student's processing style or neurological makeup. Third, interventions are *goal directed* in that they alter behaviors in a prespecified way. By stating intervention goals prior to implementation, all interested persons can agree on a mutually desirable outcome.

FIGURE 1. Flow chart of educational problem-solving steps.



Initial Concern
Clarify Concern and Select Behavioral Indicator
No
Does the Indicator Pass The "So What" Test?
Yes
Define Behavior of Concern
Identify Behavioral Dimension
Select Measurement System
Direct Measurement of Behavior in Natural Setting
Problem Validation
No

Reevaluate Problem Definition, Functional Analysis or Intervention Strategy
Data Collection and Summarization
Data Evaluation (Formative)
Is Performance Improving at an Acceptable Rate?
No
Yes
Data Evaluation (Summative)
Has the Goal Been Reached?
No
Yes
Program for Maintenance and Generalization

TABLE 1
Critical Dimensions for Defining School-Based Problems

Behavioral Dimensions

Frequency: How often a behavior occurs. This dimension is also referred to as Rate when frequency per time interval is the important cimension (e.g., hits per recess, words said per minute).

Latency: How long the time period is between the presentation of a prompt and the initiation of the behavior (e.g., how long it takes for a child to initiate compliance with a command).

Intensity: Refers to the strength of the behavior (e.g., how loud a shout is in decibels, how hard a punch is).

Topography: What the behavior looks like (e.g., if walking is the behavior, topography could refer to on one's toes, on one's heels, the bounciness of gate, etc.).

Accuracy: How correct the behavior is (e.g., correctness of math problems, free throws that go through the hoop).

Duration: How long the behavior lasts (e.g., how long a tantrum lasts, how long a student is out of seat).

Interventions as Part of Systematic Problem Solving

It is important to recognize that systematic interventions for school-based problems cannot stand by themselves. Instead, they should occur in the context of a problem-solving approach to educational service delivery. Adherence to this framework ensures the defensibility of intervention selection and ensures the intervention has a reasonable chance of remediating the identified problem.

The problem-solving model presented in this chapter combines aspects of behavioral assessment, behavioral consultation, and applied behavior-analytic models. This statement should not be interpreted to mean that behavioral approaches are the only ones that may be used with this model. Instead, this problem-solving approach provides a well articulated framework for examining problems, generating potential solutions, and monitoring outcomes without dictating treatment programs. The approach is pragmatic in that it focuses on providing effective interventions for individuals in applied settings. The approach is also dogmatic about not being dogmatic. That is, persons adopting this model must acknowledge two well-documented realities. First, the same intervention will not work with all persons in all situations. If this were the case, there would not be a need for individualized interventions. Second, there is no current technology that can predict with certainty the effectiveness of an educational intervention prior to its implementation. Therefore, professionals must monitor the effects of their interventions so changes can be made to ineffective programs in a timely manner.

The professional literature provides remarkable convergence on the components necessary to the successful implementation of this problem-solving model. The psychological (e.g., Barlow, Hayes, & Nelson, 1984), special education (e.g., Salvia & Ysseldyke, 1991; Fuchs, Fuchs, Bahr, Fernstrom, & Stecker, 1990) and school psychology (e.g., Bergan & Kratochwill, 1990; Bergan & Neuman, 1980; Elliott, Witt, & Kratochwill, 1991; Kratochwill & Bergan, 1990; Shinn, 1989) literatures all provide examples of problem-solving models that contain these elements. One of the best summarizations of these components is provided in a recent paper by Flugum and Reschly (1994) examining quality indicators related to successful educational interventions. While the presence or absence of specific quality indices does not ensure an intervention's effectiveness, their presence increases the probability a positive outcome will result.

INDICES OF INTERVENTION QUALITY

As presented by Flugum and Reschly (1994), the indicators of quality interventions include (a) a behavioral (operational) definition of a problem, (b) a direct measure of the student's behavior in the natural setting prior to intervention, (c) a step-by-step intervention plan, (d) implementation of the intervention as planned, (e) graphing of intervention results, and (f) a direct comparison of a student's post-intervention performance to baseline data. Four additional problem-solving components implicit in the preceding six-step model have been identified in the literature (e.g., Bergan & Kratochwill, 1990; Deno, 1986; Shinn, 1989). These indicators are systematic problem validation, functional analysis of the problem, goal setting, and systematic formative evaluation of program effects. Because these steps are also crucial to successful implementation of a problem-solving system, they will be included as explicit components of the quality indices for the purposes of this chapter. Thus, a nine-component problem-solving model is proposed as a best practice standard for the development and documentation of educational interventions. A flow chart depicting these components and their relationships is contained in Figure 1.

To illustrate the use of the quality indices throughout this chapter, a case example will be presented. A. J. is a 6-year-old kindergarten boy who was referred by his teacher, Ms. Stein, to the school psychologist because of disruptive behavior in school. During a meeting between Ms. Stein, A. J.'s parents, and the school psychologist, "tantruming" was identified as the major behavior of concern in school. Throughout the chapter, information regarding the evaluation of this problem and subsequent intervention will be presented. An example of how data and decision making in this case were documented is provided in the Intervention Documentation Form at the end of the chapter (see Appendix A). As you read the remainder of the chapter, it may be helpful to place yourself in the role of the school psychologist and consider how the decision-making process used with A. J. could fit into your current role.

Operational Definition

The first step in the problem-solving process is to identify and define a problem operationally. Two critical components in this process are to select and define a behavior of concern. Appropriate selection of a behavior of concern ensures that a successful intervention will result in socially meaningful outcomes. A precise definition also ensures that all involved persons will share a common understanding of when the behavior is or is not occurring. The importance of this step cannot be underestimated because "even the best intervention strategy is doomed if it is applied to an improperly defined target behavior" (Reynolds, Gutkin, Elliott, & Witt, 1984, p. 186).

Selecting a behavior. During initial problem definition, a myriad of behaviors often are identified as concerns. When this happens, which behaviors are most problematic must be clarified and prioritized, usually through an interview. Questions such as "what does Jenny do when she is defiant?" and "How do you know when Scott is feeling withdrawn?" can help generate specific examples and assist in focusing attention on behaviors of most concern. Investing time in this clarification process both ensures accurate problem identification and establishes a shared responsibility for remediating the problem.

After generating and prioritizing specific problematic behaviors, a behavior or behaviors of concern must be selected for measurement and intervention. Two components are important to consider when selecting behavioral indicators: relevance and representativeness. Relevance refers to the importance of the behavior(s) selected for intervention. Stated plainly, behaviors targeted for intervention always must be subjected to and pass the "so what?" test. Professionals must ask, if a significant change were seen in this specific indicator(s), so what? — would that change represent a socially important outcome for the individuals involved? If the answer to this question is no, then the problem must be reexamined and a different indicator or indicators selected.

Related to relevance is the issue of representativeness. In cases where a single behavior is problematic (e.g., hitting, thumb sucking), representativeness is a simple issue. The single behavior of concern can be defined directly. In cases where multiple behaviors are problematic, there are two general approaches to identifying a behavior of concern. First, in cases where a single behavior accurately reflects change in an important constellation of behaviors, a single indicator can be selected and defined. An example of this type of indicator is counting the number of words read correctly in 1 minute as an indicator of overall reading skill (i.e., Curriculum-Based Measurement). While counting words read correctly does not reflect everything about reading performance, oral reading fluency is an accurate indicator of many different components of reading, including comprehension (Shinn, Good, Knutson, Tilly, & Collins, 1992).

When a single behavior would not accurately represent the problem, it is often possible to define a group of behaviors by the effect they have on the environment. For example, if the concern is physical aggression against persons and there are multiple ways that aggression is perpetrated (e.g., hitting, biting, kicking), it may be inappropriate to choose a single behavior as reflective of aggression. In this case, it may be possible to define physical aggression as actions that could cause physical pain or discomfort to other persons in the environment and to use specific methods of aggression as examples in the definition.

Defining a behavior. The English language is full of inferential terms that appear to describe behavior but, upon closer scrutiny, could be inconsistently interpreted by different persons. Consider what is meant by the statements: Jamie acts depressed, Brett is hyperactive, and Marsha has low self-esteem. Each description appears to communicate something about an individual's behavior, but there are multiple actions or characteristics that could reflect each descriptor. As a result, two independent observers might have different understandings of the nature and severity of a concern based solely on a behavioral descriptor.

To remedy the problem of multiple interpretations, behaviors that are the subject of intervention must be described precisely. This process is called operationally defining a behavior. An operational definition must meet three criteria:

1. It must be objective, the definition should refer to observable characteristics of behavior or environmental events.

2. It must be clear, the definition should be so unambiguous that it could be read, repeated, and paraphrased by observers.

3. It must be complete, the definition should delineate both examples and non-examples of the behavior so that differences between occurrences and non-occurrences of the behavior can be discerned (Kazdin, 1982).

To write definitions with these characteristics, it may be helpful to use a standard format. A format that is particularly useful is:

> *(Target behavior)* ________________ means that *(target student action verbs)* ________________. Examples of *target behavior* include (1)__________, (2)____________, (3)____________ Non-examples of *target behavior* include (1) __________, (2) ________, (3) __________

This format requires that the intervention agent(s) attend directly to what an individual actually does when performing the behavior and provides a vehicle for efficient writing of definitions. This format also has the benefit of customizing and personalizing the description for a particular behavior, student, and setting.

In A. J.'s case, the term *tantrum* was used frequently during the initial interviews to describe the teacher's concerns. After following up these descriptions with the question "what does A. J. do when he tantrums?" it became clear that for A. J. crying was the major determinant of tantruming. He often did other behaviors along with his tantruming, but Ms. Stein could not identify an instance of a tantrum when A. J. did not cry. Moreover, there were very few cases where A. J.'s crying would not be considered as tantruming. Hence, an operational definition for A. J.'s "tantruming" in the format provided was written:

> Tantruming means A. J. **cries audibly after an adult answers "no" to one of his requests or after an adult gives him a direct command to do something.** Examples of tantruming include (a) crying when told to put away materials when it is time for lunch; (b) crying and tearing up papers when he is told by an adult to group his blocks by color; and (c) crying and throwing a toy after being told "no" when A. J. asks if he may play with a toy. Non-examples of tantruming include (a) crying after falling down at recess; (b) crying out loudly during outside activities; and (c) crying after someone says something that hurt his feelings.

This definition passes the "so what" test in that decreasing crying will allow A. J. to participate more fully in important class activities, will allow the teacher to spend more time teaching him other school-related behaviors, and may increase his opportunities for prosocial peer interaction. The definition is representative in that crying appears to be a major determinant of tantrums. Finally, this definition describes specific examples of what tantrums look like for A. J. and provides examples of what should not be counted as "tantruming."

Direct Measure of the Behavior in the Natural Setting Prior to Intervention

Once the target behavior has been defined, baseline data must be collected. This task involves establishing the relevant dimension(s) of the problem behavior, developing a method to systematically measure the behavior, and collecting data on the behavior prior to implementing an intervention.

Behavioral dimensions. Six dimensions of behavior are most frequently problematic in schools. The acronym FLITAD is a useful mnemonic device to assist in remembering these dimensions. The acronym comes from the first letter in the behavioral dimensions listed in Table 1.

To select the relevant behavioral dimension, a qualitative examination of the behavior in the natural setting must be completed. It may be helpful to ask the question "what exactly is it about this behavior that is problematic?" In some cases, the problematic dimension will be obvious. For example, the accuracy of Maria's math problems is very low or the frequency of Joe's hitting is too high. For some behaviors, there are multiple dimensions that may be problematic. For example, "tantruming" may include crying, using a loud voice, physical aggression, and noncompliance with adult directions. In some situations, the most problematic characteristic of tantrums may be their frequency; in others, duration of tantrums may be most relevant; in still others, the magnitude or intensity of the behaviors may be important. While "tantrum" might be operationally defined the same way in each of these situations, the way in which it will be measured will be different based on the most problematic dimension of the behavior.

In A. J.'s case, the most important dimension of his tantrums appeared to be duration. Ms. Stein, A. J.'s teacher, stated during an interview that the worst part of A. J.'s tantrums is sometimes they seemed to last "forever" and it made it difficult for her to teach. Moreover, when A. J. tantrumed, he did not usually become aggressive with other children, destroy significant property, or scream loudly in anyone's ear so intensity was probably not most problematic. She further stated that the number of tantrums varied on different days, but so did their duration. Thus, monitoring the number of times A. J. tantrumed probably would not have yielded meaningful results.

Behavioral measurement. Once the behavior has been defined and the relevant dimension of the behavior has been established, the behavior must be measured directly in the setting where it is perceived to be problematic. The measurement strategy used to collect information should be objective and related directly to the relevant dimension of the behavior.

TABLE 2
Five Components of the SORKC Model

SORKC Components

Stimulus — Any characteristics of or occurrence in the environment (both internal and external) that is or may be related to behavior (e.g., words on a page are a stimulus for reading).

Organism — Organismic variables that may influence behavior (e.g., hunger may influence the length of time a person attends to a reading task; learning history may influence whether a student answers a question correctly).

Response — An overt (e.g., reading out loud) or covert (e.g., reading silently) action that can be measured.

(K)Contingency — The rules of reinforcement specifying the relationships between stimuli (both S and O), responses and environmental consequences (e.g., the rule "when a reading comprehension question is answered correctly during reading group, the teacher praises the student who answered").

Consequence — The environmental events that are functionally related to the occurrence for non-occurrence) of the behavior (e.g., receiving a praise statement for a correct answer; receiving an F for not turning in one's homework.

This same strategy will be used throughout the intervention to monitor and evaluate its effectiveness at improving student performance. Therefore, the measurement strategy must be selected with care to ensure quality data collection. An extended discussion of behavioral measurement strategies is beyond the scope of the current chapter, but excellent resources are available (e.g., Alessi & Kaye, 1983; Bellack & Hersen, 1988; Epps, 1988; Shapiro & Kratochwill, 1988; Sulzer-Azaroff & Mayer, 1991).

In the initial discussion with Ms. Stein, the school psychologist suggested two different measurement strategies that might be used to monitor A. J.'s tantruming. The first option would require Ms. Stein to record how long A. J. tantrumed each day during the first 2 hours of school (the most problematic time of the day). This strategy had the advantage of only requiring measurement during part of the day but had the disadvantage of sampling A. J.'s behavior each day. The second strategy would require Ms. Stein to carry a stopwatch in her pocket and to turn it on when A. J. tantrumed and off when he stopped. This strategy's advantage was its comprehensiveness; its disadvantage was its intrusiveness on Ms. Stein's time, and the need for Ms. Stein to be present with A. J. throughout the day. Since she already spent most of the day with A. J., Ms. Stein chose to collect data on A. J.'s tantrums each day throughout the day. She was comfortable with the data-collection strategy because she "had lots of pockets to keep things in" and remembering to turn on the stopwatch would not be a problem because of how intrusive A. J.'s behavior was. The resulting data, collected across 1 week reflected the number of minutes each day A. J. had spent tantruming.

Pre-intervention data collection. After the behavioral dimension and measurement strategy have been identified, data collection can begin. Pre-intervention observation should consist of repeated measures of the target behavior over several sessions, day, or even weeks, until a stable range of behavior has been identified (e.g., no new highs or lows for three data points in a row [Sulzer-Azaroff & Mayer, 1991]). Collection of these data has three major purposes in problem solving. First, they provide a pre-intervention summary describing characteristics of individual performance such as level, variability, and trend in behavior. This summary can be used to scale the magnitude of a problem and to document pretreatment levels of behavior. Second, baseline data serve a predictive function by providing a database for predicting future performance in the absence of intervention. That is, an inference can be made about the future occurrence of the behavior if an intervention were not implemented. This prediction then serves as a standard for evaluating the effectiveness of an intervention. Third, collecting baseline data provides an opportunity to observe relationships between behavior and other environmental variables. These observations provide critical information that may be useful during functional analysis and intervention design.

To gather baseline data on A. J.'s tantruming, Ms. Stein collected data each day for 5 consecutive days. The data collected over the week ranged from 32 to 52 minutes of tantruming each day. Due to the variability during the first 5 days, data were collected for an additional 2 days, which resulted in a more stable summary of the typical length of A. J.'s tantrums. These data are depicted graphically on the intervention documentation form in Appendix A.

Problem Validation

At this point in the problem-solving process, a problem behavior has been defined and a direct measure of behavior has been obtained. A next step is to identify a context for evaluating the magnitude of the problem. In some cases, the severity of a problem will be obvious. For example, it would not take direct observation of peer performance to document that cutting other persons with a knife has a low base-rate in the typical population. In other (perhaps most) cases, the magnitude of a problem will not be apparent by examining the data alone. Whether being out of one's seat four times per hour in a fifth-grade classroom is a problem depends largely on that classroom's expectations and norms. Hence, the purpose of problem validation is to establish operationally the existence and magnitude of a problem.

A practical method for problem definition is to conceptualize problems as the difference between what is expected in an environment and what actually occurs. In practice, a discrepancy is determined by comparing an individual's current level of performance, documented during baseline data, to a performance standard representing acceptable performance. It should be noted at this point that an inference should not be made automatically that problems occur only as the result of poor student performance. Sometimes problems can occur as the result of inappropriate environmental expectations. The authors are reminded of a recent phone call from the mother of a 6-month-old who was concerned her son was not yet talking!

To address the problem of finding appropriate expectations, a most useful standard for both academic and social-emotional behaviors is based on typical peer performance. This standard is obtained by measuring typical peers' performance on a behavior of concern to find a range of typical performance. These data then can be used to quantify the magnitude of a problem, which is the difference between the target student's performance and peer performance. Using peer performance as a standard has clear advantages in educational settings. It encompasses many standards relevant to educational expectations. For example, typical peers' performance represents a standard accepted in a particular environment by a particular teacher. Typical peers' performance also takes developmental norms and expectations into account, thereby ensuring that developmentally inappropriate expectations are avoided. A response containing information about typical 6-month-old talking performance was all that was necessary to solve the problem of the non-verbal 6-month-old. Finally, a peer-performance standard is sensitive to local and regional differences in performance and expectations. Thus an individual's performance will not be evaluated in comparisons to regionally biased or unfair standards.

Though peer performance is often a useful standard in schools, other performance standards are also possible. For example, a standard set by the intervention team based on a logical analysis or on "expert judgment" might be needed in cases where typical peer performance is not available. Another standard sometimes used examines skills that an individual will need to perform satisfactorily in an anticipated future environment. The important components for all of these standards is that the desired level of performance is specified clearly, usually numerically in relation to the behavior of concern, and that the rationale for selecting a particular standard is compelling and defensible.

Once a standard is selected and operationalized, the existence and magnitude of the problem can be determined. At this point, two questions should be asked: (a) Is there a discrepancy between the target student's performance and the performance standard? and (b) If so, is the discrepancy large enough to warrant intervention? If the answer to either of these questions is no, then the existence of or severity of the problem should be questioned. The nature of the problem may need to be reexamined and redefined or further data may need to be collected to validate the problem. If the answer to both of these questions is yes, then the problem is validated and further assessment for the purpose of developing and evaluating interventions is needed.

In A. J.'s case, Ms. Stein stated that she expected no tantruming to occur during the school day but that some of A. J.'s peers also cried occasionally. During the pre-intervention data collection, the school psychologist collected data on both A. J.'s behavior and his peers' behavior. This information suggested that some of A. J.'s peers occasionally cried 3 to 5 minutes a day in a similar manner to A. J. Based on this information, there appears to be a meaningful difference between the duration of A. J.'s tantruming and his peers'. After reviewing these data with Ms. Stein and A. J.'s mother, it was agreed that further assessment and intervention appeared warranted.

Functional Analysis

Once a problem has been validated, a systematic analysis is needed to determine factors related to the occurrence, non-occurrence, and maintenance of problem behaviors. This analysis provides the critical link between assessment information and intervention procedures. Functional analysis requires careful examination of the behavior across different situations and consideration of multiple factors that may influence performance. This step is perhaps the most complex and most critical to the selection of appropriate interventions. Indeed, when an accurate functional analysis has been completed, the design of potentially effective interventions becomes less difficult.

A number of methods of functional analysis have been developed that can be used to examine human behavior (e.g., the ABC model developed by Reese, Howard, & Reese, 1977; the scatterplot method described by Touchette, MacDonald, & Langer, 1985). A particularly useful heuristic is based on the SORKC model developed initially by Lindsley (1964) and expanded by Kanfer and Phillips (1970). This model provides a conceptual structure for examining the "real world" behaviors and environments that school psychologists routinely observe in schools. Behavioral sequences are analyzed in the context of the naturalistic environments and relationships between behavior and the environment can be examined for the purpose of designing interventions. The five components in SORKC are defined in Table 2. To use the SORKC model in practice, multiple behavioral sequences are examined across time. Each sequence provides information used to summarize the environmental factors related to the occurrence and non-occurrence of behavior. As observational data are collected, patterns of relationships between behavior and the environment typically emerge. These patterns can then be analyzed and incorporated into intervention designs.

To illustrate the utility of the SORKC procedure, consider the situation surrounding A. J.'s problems. After Ms. Stein, A. J.'s parents, and the school psychologist operationally defined "tantruming" and identified the duration as the most problematic dimension, the school psychologist observed A. J. in the most problematic environment (during math activities, 25 minutes per period) and in the least problematic environment (art, 30 minutes per period) across 2 days. After observing many interactions between A. J. and adults, the following summary of the observational data was created by the psychologist (i.e., the summary comments are data-based descriptions and inferences). During the observations, three tantrums were observed during math.

- *Stimulus (Stimuli)* — Tantruming usually begins while A. J. is sitting at his desk; approximately one to two times per minute during teacher-led instruction (when all of the tantrums were observed) successive directions are given orally by the teacher usually to the whole group of 16 children; throughout math period, A. J. usually spends most of his time manipulating math materials (e.g., counting cubes, placing them in columns, grouping them, etc.); most of the time A. J. sits in the last row in the back of the classroom, typically, next to the teacher.
- *Organism* — Math activities are some of the first activities of the day and his mother stated that A. J. often does not eat breakfast (hunger could be related to current performance); A. J. has a history of having difficulty with counting and numbers (poor counting skills could be related to current performance).
- *Response* — Throughout the math class, A. J. usually does not perform the required math task correctly; when A. J. was observed to tantrum, he appeared to not understand directions; in these cases, after being given a specific direction related to the activity, A. J. begins to cry, he stops performing the math task, he speaks in a loud voice, and one time threw a math cube (manipulative) at the back wall of the classroom; during his tantrums, he usually leaves his desk and walks to a part of the classroom away from his desk.
- *K(C)ontingency* — In this case, the contingencies appear to be the rules "begin to cry during math and the teacher will talk to you" and "begin to cry during math and you can stop working on the math for a short period of time."
- *Consequence* — In all three "tantruming" instances the teacher responded to A. J.'s behavior immediately by either walking over to him, talking to him (usually to ask him to stop and to redirect him), by helping him do the activity, or by talking to him loudly from across the room, or by asking him to move to the front of the class.

The psychologist also observed A. J.'s behavior during art, where no tantrums occurred.

The school psychologist functionally analyzed the observation data using the SORKC model, applied behavior analysis principles, and professional experience. The hypothesis was developed that A. J.'s tantruming was being reinforced by the teacher's attention and by tantruming A. J. escaped from a task that may be aversive to him. Moreover, it appeared that the teacher often was being reinforced for paying attention to A. J.'s inappropriate behavior (his crying appeared to become less loud when she talked to him), thereby making her more likely to attend to him when he cried. This information was used to guide the intervention decision to have the teacher attend to A. J.'s working during math period, to ignore his tantruming whenever it occurred (unless he posed a physical danger to himself or others), to have A. J.'s mother feed him breakfast in the morning, to directly instruct A. J. in how to complete the math assignments, to modify A. J.'s math assignments so that he could complete the majority of them during group work without assistance, and to provide stickers and behavior-specific praise (attention) frequently throughout the day contingent on his appropriate behavior.

Setting Goals

After validating the existence and magnitude of a problem, a performance goal should be set. The importance of setting a goal should not be underestimated. In the absence of a clearly articulated goal, the effectiveness of interventions can become obscured. In other words, as a colleague of ours often says, "The only wrong way to set a goal is not to set one" (Julie Schendel, 1993, personal communication).

Goals are general statements about the behavior targeted for change and the direction or level that change should take (Sulzer-Azaroff & Mayer, 1991).

Goal statements are based on the problem behavior(s) and should state clearly, in a measurable way, what the individual's performance will look like if the intervention is successful. In most circumstances, a goal statement can both be stated narratively and be represented graphically on a performance chart. For the narrative statement, it may be helpful to use a standard format. A format often used for stating goals is:

> In (*number*)_______ weeks, when (*condition occurs*)________, (*learner*)______________ will (*behavior of concern to a specific criterion*)________________________.

An example of using A. J.'s tantruming is:

> In 6 weeks, when he is at school, A. J. will tantrum for less than 10 minutes per day for 8 out of 10 consecutive school days.

This goal is represented on A. J.'s performance chart by the horizontal line drawn at the 10-minute mark (illustrated in Appendix A). For a comprehensive discussion of educational goal setting, the reader is referred to an excellent chapter by Lynn Fuchs (this volume).

Written Intervention Plan

At the point where an intervention has been designed, a goal has been set, and intervention implementation is ready to begin, creating a step-by-step intervention plan based on the results of the functional analysis is the next component. The intervention plan answers questions relevant to solving the identified problem, including who will do what, when will they do it, where will the plan be implemented, how will the steps be completed, and with whom will the plan be implemented. This plan (a) ensures that all parties involved with the intervention share the same understanding of the procedures to be used, (b) serves as a guide for implementors of interventions, and (c) serves as a record of the intervention. Just as an operational definition completely describes a behavior of concern, an intervention plan clearly describes the procedures to be used during an intervention. Indeed, an intervention plan should be clear enough that a trained reader could replicate the intervention and produce the same results (Baer, Wolf, & Risley, 1968).

Schendel and Ulman (1989) identified a series of components that should be included in a written intervention plan. For academic behavior, the intervention plan should define specific teaching procedures, physical arrangements, the time allotted to each teaching activity, the materials to be used in instruction, and motivational strategies to be employed. For non-academic behaviors the intervention plan should describe the settings where the intervention will occur, motivational strategies, specific behavior management procedures, and instructional strategies.

A final component in a written intervention plan is a statement of how decisions will be made. This component describes strategies that will be used for data collection, summarization, and evaluation. Specific issues to be addressed include frequency of data collection, which strategies will be used to summarize data for evaluation, the number of data points or the amount of time that should occur before data will be analyzed, and a statement describing the actions that will be taken by intervention agents based on the intervention data (decision made).

In A. J.'s case, the intervention plan followed directly from the functional analysis of the problem and the details were worked out in a second meeting with A. J.'s parents and teacher. Data were to be collected daily by Ms. Stein and decisions about the intervention were scheduled to be made at the end of each week. Specific intervention procedures, the persons responsible for implementing them, and specific decision-making strategies are contained in the Intervention Documentation Form in Appendix A.

Intervention Implemented as Planned

Once the intervention has been designed and a plan written, ensuring the intervention is implemented as intended is the next step (Peterson, Homer, & Wonderlich, 1982). This process is referred to in the professional literature as treatment integrity (Gresham, 1989; Telzrow, this volume). There are a number of different approaches that can be used to assess treatment integrity. A teacher may be interviewed regarding the steps followed during intervention. Direct observation of intervention implementation can be completed. Or the written step-by-step intervention plan could be used as a checklist after the intervention to determine the steps that were followed. The important component in assessing treatment integrity is determining the extent to which treatments were delivered as intended so that potential effects of treatment implementation can be factored into the evaluation of treatment effectiveness. If the intervention is not implemented as designed, progress (or lack thereof) cannot be attributed to the specific plan.

Evaluating treatment integrity in practice can be a sensitive issue. School psychologists are not typically responsible for evaluating teachers' competence or professional skills, nor would most be comfortable in that role. It may be, however, part of the psychologist's role to assist in evaluating the effectiveness of an intervention. In these cases, multiple sources of influence on student performance must be considered, including the integrity of the intervention.

When interventions are not implemented as planned, school psychologists may choose to use problem-solving strategies to identify components in their control that may lead to better compliance with the intervention. These variables can be held in mind when recycling through the problem-solving process and may help to fine-tune interventions the second (or third or fourth, etc.) time through.

In A. J.'s case, treatment integrity was promoted and assessed using interviews. Prior to intervention implementation, the school psychologist reviewed with Ms. Stein the procedures to be implemented in her classroom and encouraged her to ask any questions about scenarios that were not covered by the treatment plan. Also, the psychologist suggested that she and Ms. Stein jointly review the treatment plan together again in one week to make sure everything was going as planned. At this point, the psychologist also informed Ms. Stein that if their analysis of the problem was correct and their interventions worked as expected, A. J.'s behavior would likely get worse for a short period of time prior to its improving. The psychologist also scheduled two phone calls on the following Monday to Ms. Stein's classroom as a source of support for Ms. Stein and asked the principal to drop by periodically to see how the program was working.

Monitoring of Progress and Graphing of Intervention Results

Throughout intervention implementation, student performance should be assessed frequently and repeatedly so that continuous evaluation can occur and interventions may be modified as needed. Data are collected across time on the behavior identified during problem identification. These data are used to create a graphic display for the purpose of illustrating trends in student performance that can be analyzed and evaluated.

While graphs are but one of many methods for summarizing data, they are useful for at least four reasons. First, they provide a means of efficiently summarizing information about student performance such as current levels of performance, projected performance (a performance goal), and actual performance as it changes over the course of intervention. Second, trends in performance are more easily seen and communicated when data are graphically displayed. Third, graphing of results during monitoring may have an important impact on inferences made about the intervention effectiveness and student progress (Skiba, Deno, Marston, & Casey, 1989). For example, "When parents, teachers, and other agents can see visual evidence (i.e., a graph) that a procedure is bringing about the desired change, they are likely to find the evidence reinforcing. Such reinforcement helps to maintain the participation of those people in the treatment program, which is critical if objectives are to be achieved" (Sulzer-Azaroff & Mayer, 1991, p. 128). Fourth, graphing of student performance provides a measure of professional accountability demonstrating how behavior change is functionally related to the intervention being implemented. For clarity of communication, a standard format should be used for graphs (see Parsonson & Baer, 1978; Sulzer-Azaroff & Mayer, 1991).

Formative and Summative Data Evaluation

The final component in intervention design and implementation is data evaluation and decision making. Two types of data evaluation should be conducted for each intervention: formative and summative. Formative evaluation occurs throughout the implementation of an intervention and requires the evaluator to answer the question "is this intervention working?" In most cases, effectiveness is evaluated by examining trends in performance data during intervention implementation and comparing these trends to the baseline data collected prior to intervention. Summative data evaluation typically occurs after an intervention procedure has been completed and requires the evaluator to answer the question "did the intervention work?" One systematic method of determining the effects of an intervention program is to directly compare baseline performance to post-intervention performance (Flugum & Reschly, 1994). In this case, the change in student performance across time can be determined and a comparison to the specified goal-level can be made. Again, specifics of data analysis for individual interventions are well beyond the scope of the current chapter, but a number of excellent sources are available (e.g., Kazdin, 1976; Kazdin, 1982; Marston & Tindal, this volume; Parsonson & Baer, 1978).

In A. J.'s case, the baseline data documented that his tantrums occurred an average of approximately 40 minutes a day and were somewhat variable in length. Throughout the intervention, A. J.'s performance was monitored daily and his data were recorded at the end of each day by Ms. Stein. As predicted prior to the intervention, A. J.'s tantrums increased in length immediately following intervention implementation and then reduced gradually across the next 2 weeks. After approximately 3 more weeks of intervention, A. J.'s tantrums had reduced in length on most days to below the goal level of 10 minutes per day and Ms. Stein began collecting data only 3 days per week. After 4 more weeks of intervention, a summative evaluation was conducted by holding a meeting with A. J.'s parents, the psychologist, and Ms. Stein. All persons present agreed the intervention has been successful and that A. J. appeared much happier at school. Ms. Stein agreed to continue providing positive feedback to A. J. during times when he was behaving appropriately, to informally monitor his performance, and to contact A. J.'s parents one time per week for the remainder of the semester to inform them of his progress.

QUALIFICATIONS AND CONCLUSIONS

It may seem through the illustrations presented in this chapter that school-based interventions occur in a linear, well articulated sequence. They do not. In school psychology practice, many intervention components may occur simultaneously and many of the procedures cycle back upon themselves. For example, if an initial intervention does not result in problem improvement, the intervention process may recycle back to a functional analysis for the purpose of determining how to modify the existing intervention. Another way the process is nonlinear is that some components of problem solving may occur simultaneously. The school psychologist might collect clues for a functional analysis even at the time when they are interviewing a teacher to identify a behavior to observe.

The important point in this chapter is not to prescribe a lock-step order in attending to the quality indices. Instead, it is critical that persons who provide intervention services attend to all of the quality indices *throughout* the process of service provision. Each component adds something significant to the overall picture and there are cases where the omission of any single quality index could render impotent an otherwise effective intervention.

As school psychology practitioners, the authors acknowledge that interventions are almost never as pristine as are the procedures presented in chapters such as this one. Data are often difficult to obtain or of dubious quality, persons implementing interventions may not implement them according to plan, time constraints may preclude data evaluation as frequently as would be optimal, and many other challenges will occur. Worse yet, providing these types of services may be incompatible with the structure of the service delivery model being implemented in a particular area or district.

Despite the challenges, however, using a problem-solving model to provide intervention services remains the best research-based alternative for improving individual student performance in schools. Whether students receive special education services or general education services, the procedures are equally applicable. The role of the school psychologist is changing and psychologists are increasingly being called upon to assist in problem resolution rather than problem classification. As a result, there is increasing incentive to focus more substantively on interventions and outcomes. Embracing this challenge now will both secure a place in future educational systems for school psychologists and result in improved outcomes for our constituencies.

ANNOTATED BIBLIOGRAPHY

Bergan, J. R., & Kratochwill, T. R. (1990). *Behavioral consultation and therapy.* New York: Plenum Press.
This book presents a problem-solving model within the framework of behavioral consultation. The four stages include problem identification, problem analysis, plan implementation, and program evaluation. Each of these stages is developed through a structured interview with a primary goal of developing and evaluating effective interventions.

Elliott, S. N., Witt, J. C., & Kratochwill, T. R. (1991). Selecting, implementing, and evaluating classroom interventions. In G. Stoner, M. R. Shinn, & H. M. Walker (Eds.), *Interventions for achievement and behavior problems* (pp. 99–135). Silver Spring, MD: National Association of School Psychologists.
This chapter provides an extensive review of behavioral approaches to classroom interventions. The presentation contains extensive citations to primary research and has an especially strong emphasis on factors influencing treatment selection, treatment acceptability, and teacher empowerment. Protocols for assessing treatment acceptability and treatment integrity are also included.

Graden, J. L., Zins, J. E., & Curtis, M. J. (Eds.). (1988). *Alternative educational delivery systems: Enhancing instructional options for all students.* Washington, DC: National Association of School Psychologists.
This edited book provides an excellent overview of the rationale and need for alternative approaches to educational delivery systems. Specific strategies are presented to address systems change efforts at all levels of educational systems from individual classrooms through organizational frameworks.

Stoner, G., Shinn, M. R., & Walker, H. M. (Eds.). (1991). *Interventions for achievement and behavior problems.* Silver Spring, MD: National Association of School Psychologists.
This book reflects the shift in school psychological practice toward interventions and outcomes. Chapters are written by experts in school psychology and special education. General intervention strategies are presented for a variety of academic and behavioral problems for a variety of ages (early childhood to secondary education).

Sulzer-Azaroff, B., & Mayer, G. R. (1991). *Behavior analysis for lasting change.* Fort Worth: Harcourt Brace Jovanovich College Publishers.
This book provides an extensive overview of applied behavior analytic techniques. Information concerning assessment and intervention and how to link the two are presented. Skills needed for increasing, decreasing, or maintaining behaviors or maintaining behaviors are a primary focus of the book.

Instructional Intervention Plan

Decision Making Plan: A.J.s level of performance will be summarized during ea week by determining the median performance for the week. It is expected there will be an abrupt "increase" in A.J.s tantruming then a rapid decrease (w/in the first 2 weeks) down to below 10 minutes per day. A.J.s performance will be evaluated at the end of each week, & if his performance does not match the predicted pattern, further analysis will be conducted & the intervention changed.

Student A.J. Thiimes **Goal Area** Tantrums

Phase	Instructional Procedures	Materials	Arrangements	Time	Motivational Strategies
1	*Skills and Strategies* teacher attention for appropriate working teacher-led instruction on new materials/skills modifications in math assignments (e.g. shortened)	Holt Math	regular class arrangement	30-40 min. per day	verbal praise ignoring of tantrums contingent attention
2	*Skills and Strategies* contingent teacher ignoring of tantrums A.J. will be fed in a.m. behavior-specific praise contingent on appropriate behavior	stopwatch	regular class arrangement	all day at school	Same as above
3	*Skills and Strategies*				
4	*Skills and Strategies*				
5	*Skills and Strategies*				

Definition of Behavior [Behavior– which is specific, observable, alterable and measurable– is defined then three examples and three nonexamples are provided] Tantruming means A.J. cries audibly after an adult answers "no" to one of his requests or after an adult gives him a direct command to do something. Examples include (a) crying when told to put away materials when it is time for lunch; (b) crying & tearing up papers when he is told by an adult to group his blocks by color; & (c) crying & throwing a toy after being told "no" when A.J. asks if he may play w/ a toy. Non-examples include (a) crying after falling down at recess; (b) crying out loudly during outside activities; and (c) crying after someone said something that hurt his feelings.

Dimension of Behavior [What about the behavior is problematic?] Duration

- ~~Behavior happens too much or too little (Frequency)~~
- [✓ Behavior happens too long or too short (Duration)]
- Behavior doesn't happen correctly (Accuracy)
- Behavior takes too long to begin after a prompt (Latency)
- Behavior occurs but is inappropriate or inefficient (Topography)
- Behavior is too loud, forceful, or too soft, passive etc. (Intensity)

Behavior DISCREPANCY BEFORE Intervention

- What is the student's current level of performance, the baseline? 40 min (A)
- What level of student performance would be acceptable? <10 min (B)
- What is the discrepancy between the level of A and B? 30 min (C)
- What standard is used to determine the acceptable level of performance in Item B: teacher expectation + peer performance

Standards: • Local norms [✓ • Peer performance] • Criteria for the next environment • Instructional placement standards • Developmental standards [✓ • Teacher expectation] • School policy/standards • Medical • Other--please specify]

Intervention Considerations

Beginning Date 10/17/94 (Mo Dy Yr)

Direction of Change (I,D,M) D (Increase [✓ Decrease] Maintain)

Intervention Mode (D,S,G) D ([✓ Developmental] Supplemental, Generalization)

Measurement Strategy [Who's responsible for doing the actual data collection, method of data collection, measurement conditions, monitoring schedule--frequency of data collection per week]

Ms Stein will collect observational data 2 times per week for the complete school day. The duration of A.J.'s tantrums will be measured using a stopwatch.

Behavior DISCREPANCY AFTER Intervention

- What is the student's current level of performance? ________ (A)
- What level of student performance would be acceptable? ________ (B)
- What is the discrepancy between the level of A and B? ________ (C)
- What standard is used to determine the acceptable level of performance in Item B: ________

Standards: • Local norms • Peer performance • Criteria for the next environment • Instructional placement standards • Developmental standards • Teacher expectation • School policy/standards • Medical • Other--please specify]

Outcome Data Ending Date ___/___/___ (Mo Dy Yr) # Intervention Phases ________ Discrepancy Conclusion (M,S,L) ____ (More, Same, Less)

Performance Conclusion ________________ [See code with five options below]

(1) Goal met or exceeded: Trendline slope is at or greater than slope of the goal line. (2) Goal not met but performance improved: Trendline slope reflects improvement in performance, but at a rate less than that designated by goal line. (3) Goal not met and performance did not improve or got worse: Trendline slope reflects little or no change from baseline performance or is moving away from the goal in an undesirable direction. (4) Data is not available, but the student is in school. (5) Data is not available, student has moved from school.

Student Improvement is Job #1: Goal Area Tantrums

Student's Name A.J. Thimes District Des Moines School Oxford School Year 94-95 Teacher Ms. Stein

Goal Statement: In 6 weeks, when he is at school, A.J. will tantrum for less than ten minutes per day for 8 out of 10 consecutive school days.

Expected Level of Performance: Goal Criterion (#) 10 Quarterly Objective 1 (#) ____ Quarterly Objective 2 (#) ____ Quarterly Objective 3 (#) ____ Quarterly Objective 4 ____ (Same as Goal Criterion)

Best Practices in Facilitating Intervention Adherence

Cathy F. Telzrow
Cuyahoga Special Education Service Center, Ohio

OVERVIEW

Intervention adherence is the degree to which the consultee is committed to implement a specific intervention and actively demonstrates intervention-related behaviors (Meichenbaum & Turk, 1987). Closely related to intervention adherence is *treatment integrity,* a term that defines the degree to which a planned intervention is implemented as designed (Gresham, 1989). Intervention adherence and treatment integrity have been described as mutually dependent (Reimers, Wacker, & Koeppl, 1987), and together have been the critical variable in producing successful outcomes for students within a problem-solving model (Zins & Ponti, 1990). Even though "process variables," such as compliance with an approved problem-solving sequence, may be adhered to in designing an intervention, the effectiveness of that intervention cannot be determined adequately without a defensible level of intervention adherence and treatment integrity (Gresham, 1991). As stated succinctly by Reimers, Wacker, and Koeppl (1987), "treatments that are not implemented are actually not treatments at all. The same could be true for treatments which are not correctly implemented" (p. 222).

Intervention adherence encompasses a broad range of treatment arenas, including interventions developed for individuals and families in medical, therapeutic, or counseling settings. This chapter discusses intervention adherence by educational personnel in educational settings, particularly as delivered within the context of a problem-solving sequence.

BASIC CONSIDERATIONS

Intervention adherence within a problem-solving model has been conceptualized as having two major dimensions: the degree to which critical elements of the collaborative problem-solving process are adhered to, and the degree to which the designed intervention is implemented as planned (Fuchs, 1991; Gresham, 1991). Major variables associated with each of these dimensions will be described in greater detail below.

PERSONAL VARIABLES ASSOCIATED WITH INTERVENTION ADHERENCE

Consultee Variables

Hawryluk and Smallwood (1986) identified four major reasons why consultees seek assistance in educational settings: those related to knowledge (what to do), those related to skill (how to do it), the presence of certain thoughts, beliefs, or expectations (why it is important to do it), and the presence of facilitating or interfering affects (having the emotional resources to do it). Of these four variables, knowledge and skill deficits often may be addressed directly by the consultant's adopting an educative or modeling role. In contrast, adherence difficulties that are attributed to consultee cognitions or affects must be addressed through therapeutic techniques designed to help the consultee reframe beliefs or attributions about the concern and to develop a sense of competency and self-efficacy (Margolis & McGettigan, 1988).

Besides these four consultee variables, Sandoval, Lambert, and Davis (1981) identified several process variables that relate to the consultee's successful participation in school-based consultation: understanding how consultation differs from other contacts with mental health professionals; learning how to participate in a collaborative consultation; learning the consultant's role in a collaborative context; developing realistic expectations for consultation; and acquiring self-knowledge. Sandoval et al. (1981) caution that acquiring these skills is often time consuming, but can be facilitated by careful and intensive guidance by the consultant.

Consultant Variables

The literature on effective consultations repeatedly has identified the importance of both process and content skills (Gutkin, 1986), or what has been called the "artful science" of consultation (Idol & West, 1987).

Process skills: The art. A 100-number interdisciplinary, expert panel identified 47 collaborative competencies considered critical for regular and special educators interacting to meet the needs of disabled students in integrated settings (West & Cannon, 1988). Their top 10 competencies clustered into three areas: personal characteristics, interactive communication, and collaborative problem solving. Most of the frequently cited competencies involved effective interactive communication, such as clear oral and written communication, effective interviewing and listening skills, and the ability to manage confrontation successfully.

Similar emphasis on consultant process variables was demonstrated by Knoff, McKenna, and Riser (1991), who interpreted survey data from 177 university-based school psychology programs and 307 school psychology practitioners. They identified two somewhat different five-factor solutions of consultant variables. For both expert and practitioner samples, a factor sensitive to consultation process skills — comprising such characteristics as "able to confront without personal attacks," "prompt with feedback," and "documents for clear communication" — had the highest number of items. Pryzwansky (1989) reported that no linear relationship exists between the expression of such process skills and professional experience, suggesting that personal style characteristics may be a factor in the expression of such skills. Idol (1989) has argued that teaching the "art" of effective collaboration requires a different approach from instruction focusing on knowledge or content, and she recommends careful operationalization of desired behaviors and guided practice with feedback.

Content skills: The science. Transmission of content knowledge or information outside a collaborative context (i.e., the expert consultant model) may limit consultee investment in the intervention (Witt & Martens, 1988). Conversely, implementing an effective collaborative process without knowledge or content skills may produce a group of people who feel good, but don't know what to do (McConnell & Hecht, 1991). Some authors (e.g., Zins & Ponti, 1990) suggest that content skills have been underemphasized in the consultation literature, despite the fact that student-focused and organization-focused interventions are essential in order for consultation to be effective. Fuchs (1991) reported that lack of skill in identifying and implementing interventions was a major reason why consultations failed for difficult-to-teach students in the first year of a three-year Mainstream Assistance Team project.

McConnell and Hecht (1991) conceptualized school-based interventions as a dyad consisting of strategies to address social behavior problems and techniques to remedy academic difficulties. These authors have outlined a set of core competencies, in five areas, for school psychologists in instructional intervention: assessment for intervention; the organization and provision of educational activities; effective collaborative consultation; planning, implementing, and monitoring effective intervention; and research and evaluation competencies.

Ysseldyke and Christenson (1988) have summarized the literature on instructional design into a four-pronged system: planning procedures, management procedures, teaching procedures, and monitoring and evaluation procedures. These authors' assessment system (Ysseldyke & Christenson, 1993) is designed specifically to assess the instructional environment in order to match learner characteristics with the nature of instruction, including both task characteristics and the teacher's instructional and management style (Ysseldyke & Christenson, 1991). Their research emphasizes the complex, interactive nature of instructional design, and rejects a simplistic linear model for addressing student concerns.

SYSTEMIC VARIABLES RELATED TO INTERVENTION ADHERENCE

Besides personal variables involving consultants and consultees, systemic variables can influence intervention adherence. Examples of such variables include the nature of the intervention and the facilitating structures available.

Characteristics of Intervention

Intervention adherence is influenced to some degree by the nature of the intervention itself. Characteristics of the intervention that relate to intervention adherence include complexity, degree of positiveness, and perceived effectiveness (Reimers et al., 1987).

Martens, Peterson, Witt, and Cirone (1986) found that teachers prefer treatments they can implement independently over those requiring consultation with others. This "ease of use" variable also was identified by Gresham (1989), who reported that complex treatments requiring large amounts of time, materials, or staff members to implement usually are not delivered with the same treatment integrity as those that are less involved. However, some evidence shows that the complexity of the intervention plan may interact with the severity of the problem; teachers may demonstrate a preference for complex interventions where the demonstrated problem is severe (Elliott, Witt, & Kratochwill, 1991).

A second characteristic of the intervention plan that may affect treatment acceptability, and therefore adherence, is the degree to which it is perceived as educative or positive. Clark and Elliott (1988) reported that teachers consistently favored interventions using positive (e.g., modeling-coaching) over negative (e.g., overcorrection) approaches.

In addition to the complexity and positiveness of treatments, perceived effectiveness also relates to intervention adherence. Although actual effectiveness cannot be determined without a satisfactory trial, perceived effectiveness does relate to treatment acceptability. Specifically, low levels of intervention adherence typically follow if acceptability ratings of a proposed treatment are low (Elliott et al., 1991). Conversely, teachers rated interventions portrayed as being "strong and successful" higher than those presented as weak and comparatively unsuccessful (Clark & Elliott, 1988).

Support Structures

The presence or absence of adequate support structures is another important systemic variable for intervention adherence. Examples of such supports include building and classroom climate, human and material resources, and staff development opportunities. In their description of a six-year project to enhance student discipline by moving to consultation-based child study teams, Lennox, Hyman, and Hughes (1988) identified both organizational and individual facilitators and barriers to change. Besides these factors, an internal project manager who could convey and model expectations and assign essential resources was considered central to the success of this multiyear activity.

In a thoughtful discussion of ways to increase intervention adherence by teachers, Elliott et al. (1991) recommended adopting a systems orientation. This recommendation is based on several premises: that referrals for intervention typically arise from inappropriately arranged antecedents; that child-focused consultation may not reduce teacher concerns; and that the typical consultative relationship does not promote teacher empowerment. A systems orientation acknowledges the complex influences on an identified problem, and can manipulate those ecological and programming variables that contribute most to resolution of the concern (Witt & Martens, 1988).

BEST PRACTICES

Develop Shared Mission

Although intervention adherence is influenced by numerous variables, commitment to an intervention goal or purpose appears to be central (Gresham, 1989). Such commitment is often engendered through strategic planning that identifies a shared mission or purpose.

Henning-Stout and Conoley (1988) emphasize that "for real change to occur, the vehicles for change must be presented in a manner consistent with the values of the people within the system" (p. 472). They outline a process for influencing district-wide change, the "collective investment" approach. This process, a system-wide analog to collaborative problem solving, engenders commitment to a specified objective, while at the same time identifying actions necessary to achieve an outcome. In their description of a process for implementing consultation-based service delivery, Ponti, Zins, and Graden (1988) emphasize the importance of participatory planning.

Employ Collaborative Problem-Solving Process

Developing a shared vision or purpose is critical for collaborative problem-solving. Both the collaboration (the "art") and the problem solving (the "science") are crucial (Idol, 1989). Collaboration has several key features, including a nonhierarchical relationship among the parties involved, a climate of mutual trust and open communication, and shared responsibility for design and implementation of interventions (Zins & Ponti, 1990). Systematic problem solving — consisting of problem identification, goal setting, essential preintervention data collection, and progress monitoring — is considered critical for providing effective interventions for students (Fuchs, 1991). Data from an analysis of prereferral interventions in Iowa indicated a direct relationship between the presence of many of these "quality indicators" and the effectiveness of the intervention (Flugum & Reschly, 1992).

One resource to assist school personnel in applying a collaborative problem-solving process is displayed in Figure 1. I developed this Problem-Solving Assessment and Intervention Worksheet while providing technical support to four building-level teams as part of a statewide pilot project during the 1992–93 school year. This training tool, based on the work of Batsche (1990), Graden (1992), and resources from Iowa (*Understanding Components*, 1991), among others, outlines common pitfalls at each stage of the problem-solving process, and offers possible remedies or guiding questions that consultants might use to refocus the process and ensure the presence of key "quality indicators."

In implementing effective collaborative problem solving, careful consideration must be given to the systemic structures that can enhance its implementation. While investigating a three-year study of the effectiveness of Mainstream Assistance Teams on the academic and behavioral performance of difficult-to-teach students, Fuchs (1991) emphasized the importance of including intervention-oriented structures, such as role expectations, collaborative planning time, and an individual or team of individuals to direct such an effort. In addition, careful training of individuals in both the "art" and the "science" of consultation is essential (Fuchs, 1991).

FIGURE 1. Problem-solving assessment and interventon worksheet.

Student ____________________ Grade ____ Teacher(s) ____________________

Date of Referral ____________________ Date of Problem Analysis Meeting ____________________

Collaborators ____________________ ____________________

____________________ ____________________

____________________ ____________________

____________________ ____________________

____________________ ____________________

Step 1. Behavioral description of problem (including baseline data) ____________________

Common Pitfalls	Guiding Questions/Possible Remedies
1. Concern is vague or general.	• What is it you would like ________ to do to be successful? • What would it be like if the problem weren't there?
2. Description is not behavioral.	• What does ______ look like?
3. Jumping to generating interventions before problem is analyzed.	• Do we fully understand the problem yet?
4. No baseline data on problem behavior.	• Knowledgeable team member assists in collecting data.

Step 2. Behavioral statement of desired goal or outcome ____________________

Common Pitfalls	Guiding Questions
1. Goal is vague, not in quantifiable terms.	• Would we have the goal if we reversed the description of the problem?
2. Stating the goal in "eliminative" or "dead person's" terms (i.e., absence of behavior).	• What are the replacement behaviors we would like to substitute for the problem behaviors?

Step 3. Analyze the problem by generating and testing hypotheses about why the behavior is occurring:

______________________________ occurs because ______________________________
(Problem Behavior) (Hypothesis)

Guiding Process
1. Generate hypotheses in all categories a. Curriculum b. Instruction c. School/classroom environment d. Peers e. Home/Community f. Child characteristics 2. Test the likelihood of each hypothesis by making prediction statements: If ______________________________, then ______________________________ (Positively phrased hypothesis) (Desired outcome/goal) 3. Determine need for collecting additional data to help analyze problem. *Collect only essential data.* 4. If necessary, adjourn and reconvene after essential data are collected.

Step 4. Given hypothesized reason for problem, brainstorm possible interventions.

____

____

____

____

____

____

Common Pitfalls	**Guiding Questions**
1. Evaluating ideas as they are generated. 2. Limiting suggestions to what is currently in place.	• Let's just list ideas now, and evaluate later. • If we could do anything, what intervention would we design?

Step 5. Evaluate alternatives and select intervention. (Star alternative above)

Common Pitfalls	**Guiding Questions**
1. Tendency to see a specific place or person as an intervention.	• Is that an intervention, or a place where intervention occurs?
2. Selecting interventions that are unrelated to the hypothesized reason for the problem.	• Will that intervention address the cause of the problem?
3. Giving referring teacher sole responsibility for implementing interventions.	• How can we share responsibility for implementation?

Step 6. Clarify the intervention and develop action plan, goal, monitoring procedure, and review date.

By ______________________, student will ______________________________
(Review Date) (Behavioral Goal)

as demonstrated by ____.
(Monitoring Procedure)

as a result of this intervention: ______________________ ______________________
(What and how much)

to be implemented by ______________________, ______________________
(who) (when)

and insured by ____
(treatment integrity procedure)

Common Pitfalls	Guiding Questions
1. Failure to specify goal or review data.	• What do we expect and when do we expect it?
2. Failure to thoroughly describe intervention.	• How will ______________________ (Social skills training, etc.) be implemented?
3. Failure to incorporate monitoring procedure.	• What data will we use to evaluate the effectiveness of this intervention on the review date?

Step 7. Implement the intervention and provide for long-term carryover as necessary.

Common Pitfalls	Possible Remedies
1. There is no commitment to implement plan (intervention adherence).	• Problem-solve about reasons why and develop plan to address (consider perceived effectiveness and ease of use).
2. Intervention is not implemented as planned (treatment integrity).	• Provide training, guided practice.
3. Intervention is restricted to a specialized service.	• Strategy is taught to others.

Step 8. Evaluate the effectiveness of the intervention, compare results to baseline or target goal, and continue or revise plan as necessary.

Summary of Intervention Effectiveness (Attached graphed data comparing results to baseline and target goal).

____

____

____

____

____

____

Common Pitfalls	Possible Remedies
1. Data from monitoring procedure are not available.	• Clarify/review monitoring procedure.
2. There is no evidence of treatment integrity.	• Provide for consistency in implementation through observation, self-monitoring.

Select and Specify Intervention

The literature suggests that intervention adherence may be fostered by selecting interventions that are relatively easy to implement (i.e., do not require excessive amounts of time, personnel, or materials); have perceived treatment effectiveness; and are constructive or educative, rather than reductive or eliminative (Elliott et al., 1991). Fuchs (1991) noted that for interventions to be effective they must be "feasible," a factor that varies from individual to individual, thus requiring continual redefinition. Working with other school personnel and parents, school psychologists may be in a unique position to convey information about interventions with demonstrated treatment effectiveness (Forness & Kavale, 1991).

Besides selecting interventions that are most likely to be implemented successfully, one must clarify the specifications of the intervention plan (Gresham, 1989). Intervention adherence and treatment integrity may be facilitated by completing a simple statement summarizing the planned intervention, such as that shown in Step 6 of Figure 1. A similar approach, specific to the use of contingency contract procedures, is illustrated by Fuchs (1991).

As is implied by the possible pitfalls and guiding questions associated with Step 6 in Figure 1, the specific nature of the intervention must be described and understood clearly by educational personnel (Fuchs, 1991). Generic descriptions of an intervention, such as "social skills training" or "differential reinforcement of other behavior (DRO)" are not adequate to ensure standardization of treatment (Gresham, Gansle, Noell, Cohen, & Rosenbaum, 1993). Some successful programs have developed specific treatment protocols for commonly employed interventions (Fuchs, 1991; Willis & LaVigna, n.d.). These protocols provide a written, step-by-step guideline for implementation of specific interventions. Often these should be accompanied by additional supports, such as those described in the following section.

Provide Support Structures

Successfully designing, implementing, and maintaining interventions to address students' academic and behavioral problems is a complex and sometimes fragile process. Zins and Ponti (1990) identified several characteristics of the process that, being nonreinforcing for consultees, may produce resistance. Part of the responsibility of effective consultants is to anticipate each barrier and to employ appropriate support structures (Margolis & McGettigan, 1988).

Physical/cognitive supports. One example of physical or cognitive supports that can enhance intervention adherence is the delivery of modeling and guided practice in implementing specific academic or behavioral interventions (Margolis & McGettigan, 1988; Zins & Ponti, 1990). In my experience, treatment integrity is often directly related to an incomplete or inaccurate understanding of how to implement a specific treatment. Even concepts that appear relatively straightforward (e.g., ignoring problem behaviors) may require demonstration and feedback so that they are implemented correctly.

A second consideration is the recognition and arrangement of systemic structures to facilitate effective school-based interventions. The provision of such supports relates directly to the first two elements, a shared mission and a collaborative process. Witt and Martens (1988) suggested that one cannot assume "that a clear cut solution exists for each and every classroom management problem, and can be applied independently of ongoing instructional practices" (p. 212). This view was expanded by Martens and Kelly (1993), who emphasized that desired student behavioral outcomes are fostered not through isolated treatment strategies, but through an effective instructional program that serves as a vehicle for stimulus control.

As Elliott et al. (1991) emphasized, effective interventions often require modification of system variables. These authors reject an intervention model that adopts a simplistic problem-to-treatment sequence, and advocate instead a system of teacher empowerment that recognizes the complex ecological framework in which educational interventions occur. One intervention model that incorporates systems change and teacher empowerment is the Comprehensive Classroom Management Project (*Strategies for Developing*, 1992). Developed by a statewide task force of educators and parents in Ohio, and piloted in several districts across the state during 1992–93, the Comprehensive Classroom Management Project "recommends that school districts adopt a systemic, positive, proactive, and instructional approach to classroom management" (p. 5). Development of school-community partnerships and systematic building-level collaborative problem solving are important components. The planning guide argues that rather than implementing short-term, reactive strategies to address behavioral concerns, schools should examine ecological variables that contribute to student discipline problems, such as school climate, aspects of curriculum and instruction, and formal discipline procedures.

Psychological/affective supports. Intervention adherence sometimes is impaired by the interventionist's beliefs or attitudes about the student, himself or herself, or the work setting. In such instances, the school psychologist may facilitate interventions by providing psychological or affective supports.

Analyzing the research on managing resistance in implementing interventions in mainstreamed classrooms, Margolis and McGettigan (1988) outlined several key considerations for consultants. Among these are the provision of interpersonal support, such as empathy and encouragement. Recognizing and understanding the enormous stress of working with students with significant academic or behavioral challenges may help overcome teachers' resistance. Offering concrete or therapeutic strategies for stress reduction, such as time for dialogue, relieving a teacher periodically, or occasional team teaching, goes a long way in conveying to teachers the true sense of "shared responsibility."

Employ Effective Monitoring Systems

By employing effective monitoring systems, such as those described below, the integrity of interventions can be enhanced (Elliott et al., 1991). Such mechanisms can help identify the need for additional supports for intervention adherence and treatment integrity.

Observation. Periodic structured observations during the course of intervention can identify barriers to intervention adherence and treatment integrity. Gresham (1989) delineates three steps to determine the integrity of interventions: explicit specification of the intervention components; direct observation to identify the occurrence and nonoccurrence of each component; and computation of the percent of intervention components implemented, to derive an index of treatment integrity. Additional considerations include the number of observations necessary and the effect of the observation itself on the implementation of the intervention.

Self-monitoring. Incorporating a self-monitoring strategy into the treatment program also may facilitate intervention adherence. Gresham (1989) provided an example of a self-monitoring procedure designed to assess and enhance treatment integrity. But he cautioned that such methods may be difficult to implement in some classroom setting because of competing activities.

Program Status Report. LaVigna, Willis, and Sweitzer (1990) have developed a specific strategy to enhance intervention adherence and treatment integrity for personnel working with individuals with moderate to profound developmental disabilities. This technique employs a systematic checklist of the program components considered important for the target student. Called the Program Status Report (PSR), this checklist is developed via consensus by interventionists, and is completed regularly through self-monitoring or through observation by a consultant. Illustrative program components incorporated into the PSR include current individualized education programs (IEPs), written behavioral plans, and regular monitoring data. The standards reflected on the PSR must be essential yet realistic program elements that are explicitly defined and verifiable through direct observation or permanent product (LaVigna et al., 1990).

Use of the PSR enables one to identify discrepancies between desired program components and actual characteristics of the intervention, and to seek remedies. LaVigna et al. (1990) have reported that systematic use of the PSR can enhance staff consistency in implementing interventions. Furthermore, they have identified a direct relationship between such staff consistency and client behavior. Specifically, if staff consistency ratings on the PSR are 85% or higher, problem behavior in populations of individuals with severe challenging behavior is reduced dramatically.

Incorporate Review/Trouble-Shooting Mechanism

When effective monitoring systems, such as those just described, are employed, problems with intervention adherence and treatment integrity often can be identified. However, without the inclusion of a review or trouble-shooting mechanism, it is difficult to design a viable remedy for the situation. The problem-solving process incorporates a review step to examine monitoring data and determine whether to continue or revise the intervention (see Figure 1, Step 8). This review must examine not only student outcome data (i.e., the progress toward the identified student goal), but also data describing the degree of intervention adherence.

SUMMARY

For the effectiveness of a given intervention to be determined, it must be implemented actively (intervention adherence) and correctly (treatment integrity). Inadequate attention to these two critical elements may produce erroneous conclusions about the effectiveness of specific treatments of students' school-related problems (Gresham et al., 1993).

In the context of educational consultation, intervention adherence may be influenced both by personal variables, such as the behavior of consultants and consultees, and by systemic variables, such as the nature of the intervention and the presence or absence of certain support structures. Intervention adherence and treatment integrity can be facilitated by the following practices:

- Employment of participatory planning to create a shared vision for the education of students and the design of intervention;
- Implementation of collaborative problem solving that engenders commitment to the intervention and incorporates key predictors of intervention effectiveness;
- Selection of interventions that are both feasible and effective and the careful specification of strategies so they are clearly understood by interventionists;

- Provision of both cognitive (e.g., information, training) and affective (e.g., encouragement, empathy) supports, preferably within an ecological framework;
- Incorporation of effective monitoring systems that can determine whether designed interventions have been implemented actively and correctly;
- Employment of formative and summative evaluation, to ascertain the need for revision in variables in order to improve intervention adherence and treatment integrity.

Walker (Eds.), *Interventions for achievement and behavior problems* (pp. 99–135). Silver Spring, MD: National Association of School Psychologists.
This chapter provides a review of research related to selecting, implementing, and evaluating the effectiveness of educationally-based interventions. It outlines variables associated with treatment acceptability and advocates a model for enhancing teacher empowerment and intervention compliance. The chapter concludes with a thorough discussion of issues related to treatment integrity.

Gresham, F. M. (1989). Assessment of treatment integrity in school consultation and prereferral intervention. *School Psychology Review, 18,* 37–50.
This article provides an excellent summary of the literature on treatment integrity. It describes factors associated with treatment integrity in educational settings, and illustrates strategies for evaluating treatment integrity.

Understanding components of the problem-solving process: A collection of information papers to assist professionals. (1991, January). Des Moines: Iowa Department of Education.
This resource consists of 10 information papers focusing on various aspects of problem solving. Developed by a council of instructional and support service representatives from the Iowa Area Education Agencies, this collection provides a concise but substantive introduction to the key indicators of effective student interventions.

Zins, J. E., & Ponti, C. R. (1990). Best practices in school-based consultation. In A. Thomas & J. Grimes (Eds.), *Best practices in school psychology-II* (pp. 673–693). Washington, DC: National Association of School Psychologists.
This chapter provides an excellent overview of school-based consultation, including sections devoted to collaborative problem-solving and intervention assistance process. Intervention effectiveness and follow-up are discussed, including a summary of the literature on intervention adherence and treatment integrity.

Best Practices in Program Modification and Exit Decisions

Julie Schendel
Joe Ulman
Iowa Department of Education
Lakeland AEA 3, Cylinder, IA

OVERVIEW

This chapter describes a strategy to determine when to alter special education programs and services in both academic and nonacademic areas. Decisions related to program modification represent extremely important judgments concerning the appropriateness of ongoing special educational programming. Included in those decisions are questions regarding when to modify the type or intensity of programming being offered as well as when to exit a student from all assistance. Guidelines in both areas will be offered.

The regulations of both Public Law 94-142 (the Education for All Handicapped Children Act of 1975) and the Individuals with Disabilities Education Act (IDEA, 1990, Public Law 101-476) provide limited assistance in program modification and exit decisions. Only initial placement decisions receive considerable attention (for example see Section 300.533, CFR or Section 1412 of IDEA). Other program modification issues, such as exit criteria or the basis for changes in the level of special education service a child should be receiving, are omitted. Instead it is only indicated that programs will be evaluated at least annually (IDEA stipulates they be "reviewed" every six months) with limited structure offered regarding what is to be contained in that effort (see Section 300.552, CFR or Section 1477 [b] of IDEA).

Likewise, little help is available in the educational literature regarding special education program modification and exit decision-making. An earlier document by the authors, *Performance Monitoring of Academic and Non-Academic Behaviors* (1990), provided methods for determining student change in both academic and nonacademic behaviors. Although useful in deciding when to change or modify a specific intervention, the document did not address program modification and exit issues.

Allen (1989) suggested two possible reasons why program modification and exit appear so infrequently in the literature. First, he hypothesized that data typically are not collected on student exit from special education because it is not a common event. A second hypothesis was related to the possibility that sufficient data were not available regarding student performance to allow program modification and exit decisions to be made reliably. Both explanations have been consistent with the authors' experience. For example, decisions related to program change have been based upon published achievement and ability tests. This information has been collected infrequently and analyzed unsystematically — typically during annual review meetings. Because of the lack of a curriculum match between published test content and classroom expectations, predictions of student success in a different environment have been impossible.

Although these hypotheses are plausible, it is the authors' opinion that a more problematic and pervasive explanation exists for the lack of information and guidance on program modification and exit issues. This hypothesis suggests that there is a fundamentally flawed philosophy within the educational community regarding the nature of student skill deficits and disability. Traditionally, disability has been viewed as an internal trait of the student and has provided the basis of eligibility and placement within special education programs and services. Within this philosophical viewpoint, disability has been seen as being within the child, permanent, and virtually unalterable. If appropriately identified (truly disabled), children have been expected to make limited growth and to require long-term assistance. Although remediation of the symptoms of the disability has been the focus, it has been accepted that, once identified, a student would in all likelihood, have the disability for at least his or her academic life and therefore would be continually eligible for (and therefore placed in) special education. Given the invariable nature of a disability in this type of belief system, significant effort has been focused upon initial eligibility issues, with complex formulas being developed to ensure that only the truly disabled are served. Also because of this orientation, sensitive data regarding student progress and special education exit criteria have not been a central issue. Actually, improvement in a student's skills to a level which put the student in "jeopardy" of losing special education eligibility often has resulted in Individualized Education Program (IEP) teams developing new and innovative areas of need which had less measurable criteria for eligibility (e.g., study/organizational skills) and would therefore allow the student to continue in the program.

In contrast, the model presented in this chapter views the issues of disability and need as being identical. Students' need for assistance defines their eligibility for service. There is no search for internal traits to determine disability. "Disability" status is assigned when a child's performance is found to be sufficiently different from peer performance to require specialized services not available in the regular education setting. Likewise, program modification and exit are based upon a similar analysis of the degree of need shown by the child when compared to peers. If, over a designated period of time, a student is found to be resistive to intervention attempts or, conversely, is found to reach a performance level acceptable within a less restrictive education setting, program modification or exit is initiated. The degree of special assistance is determined through analysis of the student's actual performance. This "performance monitoring" approach is consistent with, and discussed in depth in a chapter within this book (see Marston, Performance Monitoring).

BASIC CONSIDERATIONS

Why Are Students Continued in Special Programs?

There appears to be a number of reasons why students are maintained within a special education setting after they have made sufficient progress to have their programs modified. The following represent a partial listing.

1. *Lack of reliable data.* Perhaps the most frequent reason why students remain in a more restrictive setting than they require is simply that no one collects the correct data to determine their educational needs (Allen, 1989). Information about student performance most readily available to IEP teams at the time of program reviews is usually published, norm-referenced test results. This type of information has been found to be virtually useless in making significant program decisions about children (Jenkins & Pany, 1978; Good & Salvia, 1987), because it does not describe a student's growth over time and because the comparison group is a national sample rather than the more appropriate norm group of the less restrictive environment.

2. *Lack of communication systems between regular and special education staff.* In some circumstances, students are maintained in special education settings because there is a lack of systematic communication between regular and special education personnel. Often there is a perception by special education staff that if a child is exited from the special education program, coordination between programs will be limited and the techniques necessary for success will not be used. In these circumstances, a child is seen as needing to be completely able to function in a regular setting with no regular education modifications (a standard which is not met by many regular education students).

3. *Transitions.* Occasionally, students are maintained in special education due to an upcoming transition (elementary to junior high, movement from one building to another, change in teaching staff, etc.). There is a fear that if the child is exited at this critical time, progress may be lost and the child's skills may suffer. Rather than develop a support strategy to minimize the effects of the transition, teams determine that "now is not the time."

4. *Lack of clearly defined goals.* When goals for determining success are defined loosely (e.g., grade-level reading skills, recommendation of the IEP team, etc.), students are maintained in special education because any positive growth is seen as a measure of program success. In these circumstances, IEP teams may take an "if it ain't broke, don't fix it" orientation toward exiting students. Without criteria for successful re-entry into a less restrictive environment, the question of exit is never seriously discussed.

5. *Over protection/learned helplessness.* When special education programs take on the role of "protecting the disabled students" from the expectations of a less restrictive setting, students are placed into a circumstance that makes it difficult for them to return to such a setting. Goals for student performance must be anchored in functional skills demanded in the target setting.

6. *Current funding formulas.* Under the funding procedures in many states, school districts are provided added money to serve students within their districts who are identified as disabled. Special education teachers are often paid from those funds. If too many students are exited from a program, the amount of special education dollars available in the district might be less than the amount needed to hire the teacher. This procedure adds an unfortunate pressure to the decisions regarding the exiting of students from special education.

7. *Reinforcing nature of continued placement.* Those students currently being considered for exit from the special education setting are typically those evidencing a great deal of progress. These are usually

the same students who are the most rewarding for the special education teacher to maintain (achieving their goals, positive self attitude, etc.). This adds a disincentive for the special education teacher to exit the student from the program.

8. *Lack of knowledge of regular education expectations.* Typically, special education personnel do not know what is expected of a regular education student within a specific classroom. It is difficult to recommend exit from a special program entirely without a clear understanding of the typical performance level within the regular program.

9. *Parent request.* In some circumstances, parents will request that their child be maintained within the special program. Often this is because of the difficulties their child had in regular education prior to the provision of special education. Often, the data necessary to reassure parents by showing them how their child's performance compares to regular education classroom performance are lacking.

BEST PRACTICES

In the absence of specific legal guidelines and empirical research, the following procedures are suggested as an approach to program change.

When Should Program Change Be Considered?

One of the topics for discussion at annual review meetings is the pupil's need for continued special education placement. In the past, this annual review might have offered the only opportunity for considering a placement change due to the fact that it was the only time during the academic year when an attempt was made to formally measure a student's progress toward long-term goals. Although teachers might have regularly collected information on a student's acquisition of short-term objectives, a more comprehensive assessment of progress needed for placement decisions might have occurred only at annual review time. Under this traditional system, some students may have been maintained in special education placements longer than necessary simply because of a lack of comprehensive, long-term data at an earlier date.

The adoption of a performance-monitoring approach to evaluating student progress offers more frequent opportunities to consider a possible change in placement. Because student performance data are collected and analyzed continuously, recent information is always available about a student's progress toward long-term goals. If the data suggest that long-term goals have been achieved, consideration may be given to a change in placement at any time.

What Factors Should Be Considered in Determining Whether a Placement Change Is Warranted?

The evaluation which resulted in a student's placement into a special education program was multifaceted and comprehensive. Ideally, it should have examined not only student variables such as motivation and mastery of academic subskills but also characteristics of the curriculum and learning environment. These same factors need to be considered when making a decision about changing a student's placement. Each of these factors will be considered in turn.

Student variables. One important factor suggesting that a placement change is warranted is demonstration of improvement in the deficit area(s) that first prompted a student's placement in special education. For example, a placement change might be warranted for a student who has shown significant decrease in disruptive or aggressive behaviors, if these were the deficit areas originally identified as educational needs. Two questions need to be answered in order to determine whether sufficient improvement has been shown to warrant a change in placement:

1. Has the student met his or her IEP goals?

2. Is the student performance sufficient to meet the expectations of an alternate setting or, in other words, is the student functioning at a level similar to that of peers in the new setting?

The first question requires an individually referenced comparison that examines an individual student's rate and level of performance at different times under different instructional conditions (e.g., regular classroom instruction vs. resource room instruction). If a given instructional placement has been beneficial, then the student's level of performance should have changed to be similar to that prescribed by the IEP goal. In other words, the student's performance should be better than it was prior to the implementation of a given program.

A satisfactory response to the first question, however, is not enough to suggest that a change in placement is appropriate. The attainment of a specific IEP goal does not always mean that the student has sufficient skills to meet the expectations of an alternate setting. Most frequently, students are placed in special education programs because their performance is significantly discrepant from that of peers. For students who demonstrate very significant deficits in skills, the attainment of a given IEP goal may represent only a partial reduction of the initial discrepancy that warranted a special education placement. These students may continue to require special education services until their discrepancy in skills has been significantly reduced or eliminated.

The expectations of an alternate setting (i.e., the mainstream) are usually defined in terms of local norms. The second question, then, requires a norm-referenced comparison of an individual student's performance with that of a particular peer group. Don Allen (1989) describes two different comparisons which might be made to peer groups in the mainstream setting. First, the most common comparison might be made to "average" peers or the "average level of functioning" within a given classroom or grade level. It has been suggested, however, that this comparison might be too strict a standard because not all students in the mainstream perform exactly at the level of "average" peers. A more reasonable expectation might be defined by a comparison to lower functioning students within a classroom. For example, a reasonable performance expectation might be defined as an oral reading rate similar to that of students in the low reading group. While this level of performance is likely to be lower than the "average" for a given classroom, it may be viewed as describing the minimum level of performance necessary to be successful in the mainstream setting.

As student performance approaches that level of the IEP goal and mainstream expectations, the question arises as to how consistently or for how long a period of time the student must demonstrate this level of performance before a change in placement is considered. Unfortunately, at the current time, there is no empirical answer to this question. Obviously, it would be expected that the student demonstrate the appropriate level of performance with sufficient consistency to prove that its attainment was not just a fluke. At the same time, requiring the student to demonstrate a given level of performance for too long a time may delay an appropriate change in program. As a rule of thumb, IEP teams may wish to initiate consideration for a change in placement as soon as student performance begins to approximate defined levels. As the team formulates a plan for change, student performance can continue to be monitored and, if the team feels that a sufficiently stable pattern of behavior has been demonstrated, the program change can take place.

The attainment of a defined level of skill is probably the first variable that IEP teams will examine when considering a change in placement. However, it should not be the only one. Not only must a student have acquired a given skill, he or she must also be able to demonstrate that skill in the new setting. To demonstrate a given skill, the student must have acquired what are broadly termed "classroom survival skills" such as attention to task, organizational skills, and work completion rates. A data-based examination of student performance in comparison to peers will provide the IEP team with useful information about the degree to which a student might be successful in the mainstream setting and also about which skills the student needs to acquire and/or demonstrate consistently. Some students will require specific instruction in classroom survival skills as well as instruction in academic areas. Other students may be competent to perform a given skill but may have difficulty generalizing a given behavior to a different setting.

When considering whether deficits in classroom survival skills exist, the IEP team needs to consider the range of peer performance within a given setting. Some students will demonstrate a high level of functioning, while others will function at a much lower, but still acceptable, level according to classroom standards and teacher expectations. For example, some students may remain on task virtually 100% of the time, while others may be on task only 75–80% of the time. To avoid establishing unreasonably high standards for an individual student, the team may wish to define a minimum level of acceptable performance for a given behavior. This standard might not represent a high level of functioning or even an average level of functioning for peers but would still be within the range of acceptable performance.

If deficits in classroom survival skills exist, the IEP team is faced with the choice of either maintaining the student in special education until the appropriate skills have been acquired, or changing the student's program to an alternate setting and providing support and skill training in that setting. If the student enters the new environment without a given survival skill, not only will he or she require instruction and support, but also the new environment must be willing and able to make modifications for the student that will allow him or her to be successful until the new skill is acquired. It might be argued that many students would find it easier to learn a skill in the setting in which it is expected to be used rather than attempting to generalize a skill from one environment to another.

Some questions which need to be considered as the IEP team examines classroom survival skills are

1. How well is the student able to maintain attention on a given task and remain undistracted, not only in small-group settings but also in large-group activities and independent-study periods?

2. How well does the student make use of work time? Does the student begin work on a task promptly and without individual attention from the teacher?

3. What is the student's rate of work completion? Can the student complete a given task within a reasonable amount of time?

4. How is student performance in the area of assignment completion? Does the student take responsibility for completing assignments or are frequent reminders and monitoring necessary in order for the student to follow through?

5. Does the student ask for help when necessary, and is the student able to do so appropriately? Does the student attempt to resolve problems independently or does he or she ask for help excessively?

6. How are the student's organizational skills? Does the student remember to bring necessary books and supplies to class? Does the student keep track of assignments and remember to turn them in on time?

7. Does the student demonstrate appropriate classroom behavior? Does he or she follow rules about raising one's hand before speaking, cooperating with other students, and the like? Are there any problems with behavior in other settings such as the hallway, bathroom, lunchroom, or playground?

8. How well can the student follow oral and written directions? Does the student attend while directions are presented? Must directions be repeated, shortened, or somehow altered for the student to understand?

9. How are the student's social skills? Does the student interact appropriately with peers and adults? Can the student take turns, share materials, handle teasing or criticism, and so forth?

10. How appropriately does the student participate in group activities? Does the student attend during group discussions? Does the student volunteer pertinent ideas and answers? Does the student take an active role in group projects?

A final student variable necessary to consider when discussing a placement change is the student's attitude toward the change. Some topics to discuss with the student include expectations for success or failure in the alternate setting, concerns or fears about making the change, and the types of assistance the student might feel are necessary to be successful in the new program. A similar discussion with the student's parents might help to identify factors which need to be addressed prior to or after a change in placement.

Curriculum-instructional-environmental variables. Examining student variables alone is not sufficient to determine whether a placement change is appropriate or whether the student can be successful if such a change is effected. The IEP team also needs to assess the degree of similarity in the curriculum and instruction between the special education and regular education environments.

For some students, particularly those with more severe skill deficits, curriculum materials and instructional procedures used in the special education setting may be significantly different from those used in regular education. Alternate curriculum materials may introduce new skills in a different sequence or manner than the regular education curriculum, may provide more opportunities for practice of one skill before another is introduced, or may emphasize one approach to learning a skill rather than another (e.g., a phonetic approach to reading rather than a sight word approach). Instructional procedures used in the special education setting may involve more frequent teacher attention, behavioral prompts, and models and cues for a given skill. More immediate feedback about performance may be provided, along with error correction practice and a frequent schedule of reinforcement (Lentz & Shapiro, 1986). Even though a student may have made significant improvement in a skill, and even though performance monitoring using regular class curriculum materials may have indicated that this skill was generalizing, the student may not be able to maintain an appropriate rate of continued skill development if curriculum and instructional procedures are changed abruptly.

Caren Wesson (personal communication, January 9, 1990), Associate Professor at the University of Wisconsin-Milwaukee, has suggested that, prior to making a change in placement, efforts should be made to modify curriculum and instruction in the special education environment to more closely resemble those which will be found in the new environment. For example, instead of working in a special reading curriculum, the student may instead be placed in a specific level of the basal reading series used in the regular classroom. Instructional procedures may be altered to involve less one-to-one contact from the teacher and more small group and/or independent study activities instead. The schedule of reinforcement for assignment completion or accuracy may be significantly reduced. However, monitoring of student performance should continue to determine if the student's rate of progress slows or ceases with the new regimen. If such a decrease in improvement is demonstrated, the team may wish to examine the degree to which regular class instruction and/or curriculum materials can be altered to more closely approximate special education methods and better meet student needs. If such modifications are not feasible, the team may decide either that a slower rate of progress is acceptable, given the benefits of increased integration, or that a change in placement is not appropriate at this time.

Other environmental demands need to be assessed when considering a program change. The relationship between these environmental variables and classroom survival skills is of particular importance. Different classroom settings make different student demands and the survival skills necessary to be successful in one setting may be very different from those necessary to be successful in another.

Epps, Thompson, and Lane (1985) describe a number of factors which should be considered in evaluating a given environmental/classroom setting. They include the following:

1. Classroom routines and activities: What is the sequence in which specific classes are taught? What are the expectations for the appropriate use of free time? What are the procedures for changing from one activity to another or for preparing to go home in the afternoon?

2. Physical arrangement of the room and available materials: How are student desks arranged? Where is the teacher's desk? Where are storage spaces, study carrels, activity centers, chalk boards, bulletin boards, and other equipment used in the room such as computers, overhead projector, or tape recorders?

3. Behavioral expectations of the teacher: Which behaviors does the teacher emphasize and reinforce, and which does the teacher particularly dislike?

4. Types and amount of reinforcement available: Does the teacher use edible, tangible, token, social or activity reinforcers? For which behaviors are students reinforced? What is the schedule of reinforcement?

5. Methods used by the teacher to decrease or respond to inappropriate behavior: Does the teacher use time out, ignore inappropriate behavior, differentially reinforce appropriate behavior or use a response cost technique?

6. Goal setting: Are the goal structures cooperative, competitive, or individualistic?

7. Instructional materials and equipment: Does the teacher use a chalk board, overhead projector, chart, or map to illustrate points? Are other audiovisual materials used such as films, filmstrips, tape recorders, or records?

8. Instructional methods: What are the grouping patterns for various subjects, nature of assignments, manner in which directions are presented, opportunities for additional skill practice?

9. Basis of student evaluation: Are students graded on daily work, tests and quizzes, class participation, behavior, or some combination of these factors? How are assignments corrected and how soon does the student receive feedback on performance?

A careful examination of these environmental factors should assist the IEP team in identifying specific classroom survival skills which the student must possess to be successful in a given environment. If certain survival skills are lacking, efforts should be made to provide instruction and support in order to change student behavior to more closely match the expectations of the environment. Equal consideration should also be given to making environmental changes that will more closely match identified student needs. A change in placement is most likely to be successful if attention is devoted to student variables as well as curriculum/instructional/environmental variables.

How May the Transition from One Program to Another Be Accomplished?

As performance in the special education setting begins to approximate that described by IEP goals and the normative performance of peers, the IEP team should consider formulating a plan to transition the student from one program/environment to another. Consideration of the factors just described should enable the IEP team to determine the degree to which the student is ready for and likely to be successful in a different program. It should also enable the team to determine the degree to which the new environment is ready to receive the student and make accommodations for the student's needs.

In some cases, the results of an evaluation of student skills and environmental factors may make it clear that a change in program is appropriate and the transition can be made almost immediately. In this circumstance, the transition plan may involve little more than determination of the time line by which the change will occur. In other cases, an evaluation may indicate that the student and/or environment is not yet sufficiently ready for the transition. In this circumstance, the IEP team may choose either to continue the current program for the time being with no further consideration of a program change or to formulate a transition plan that will better prepare the student and the environment for the program change.

A transition plan is most likely to be successful if its formulation is a team effort involving the input of all concerned parties including the student, parents, special education teacher, receiving teacher, and all support staff who will provide assistance in one capacity or another. The transition plan should specify a period of time in which all parties will work on enhancing skills and environmental factors that will increase the likelihood of student success in the new environment. For some students, the team may choose to maintain the current environment while the transition plan is in effect.

As is the case throughout program planning, the transition plan should include objective, measurable goals to be accomplished by the student and/or the environment. With regard to student variables, these goals might include such factors as the maintenance or continued improvement of performance in IEP skill area(s) or improvement in specific classroom survival skills. With regard to the environment, goals might involve changes in instructional procedures or curriculum materials, the provision of a motivational strategy, or some alteration in the physical arrangement of the new setting. Time lines for the accomplishment of specific tasks should be established as well as a monitoring procedure that will facilitate data-based decision making about the plan's success. For a student who continues to be served in a special education program, the transition period may also provide opportunities to participate in the new environment. These experiences will not only allow the student to become more familiar with the new setting but also offer an opportunity for the team to assess skill generalization in the new environment.

At the conclusion of the transition period, the IEP team may use information from ongoing performance monitoring to determine the success of the transition plan. If transition goals have been accomplished, the team can then proceed with the program change.

How May the Success of the Program Change be Evaluated?

Unfortunately, at the current time it is not possible for IEP teams to predict with 100% accuracy that a program change will be successful. At best, teams can do a careful evaluation of the student and environment and use this information and their professional judgment to make what they consider to be an appropriate recommendation. A recommendation for a program change, like any other recommendation for a program placement or for a specific intervention procedure, should be treated as a hypothesis to be tested. Student performance should continue to be monitored and the IEP team should use this information to judge the success or failure of the planned change.

At the time that a program change is made, the IEP team should specify performance goals and a monitoring plan. They should also specify some points in time at which they will reconvene to evaluate the outcome of their recommendations for change. For some students, it may be important to conduct a follow-up review as the student transitions from one class to another at the beginning of a new academic year. This review might involve providing the student's new classroom teacher with information about instructional modifications used in the previous year and doing some evaluation and training in a new set of classroom survival skills for the student. In the Minneapolis Public Schools, a follow-up review of the student's performance is also conducted within one calendar year of termination from a special education program (Magnusson & Schuster, 1986).

When the IEP team convenes to evaluate the outcome of a program change, the following questions should be considered:

1. In comparison to the student's previous performance, has he or she continued to make progress in the specific deficit area(s) which initially prompted the provision of special education services? If so, is this progress at a satisfactory rate?

2. In comparison to peer performance, does the student continue to function within the normative range? That is, does student performance continue to be at a level similar to that of a defined peer group?

3. Does the student continue to demonstrate satisfactory performance with regard to important classroom survival skills?

4. What are the attitudes of the student, parents, teachers, and other staff members regarding the change? Are these parties satisfied that the change has been successful or do they have specific concerns which need to be addressed?

The answers to the first three questions should be data-based, allowing an objective evaluation of the degree to which a program change has been successful. Responses to the fourth question are also important, although more subjective, and the statement of specific concerns may provide ideas about factors which need to be addressed to make the program change more successful.

If it is the judgment of the IEP team that a program change has not been successful, a return to the original special education placement should not be the only option considered as a solution. The team needs to identify specific factors which led to the lack of success and then devise an intervention plan to address the factors. Once an intervention plan has been devised, it is up to the IEP team to determine the site(s) in which this intervention plan will be carried out. In some cases, this site may be the original special education program; in other cases, a less restrictive special education program may be recommended or even a continuation of the current program with additional support. Performance monitoring can continue to provide information about the success of any program changes recommended by the IEP team.

SUMMARY

Any program change represents an important milestone in a student's educational career. Although initial placement decisions have historically received significant attention, questions related to program modification and exit have lacked adequate answers. Too often, the minimal standards included in special education law have defined the time lines and content of program review procedures. We cannot continue to accept yearly inspection of student progress as the method for program decision making.

The strategies for program modification and exit described in this chapter offer a problem-solving approach as part of a larger system of data-based decision making. "Exit is linked to entrance as well as to monitoring of the effectiveness of instruction strategy" (Allen, 1989, p. 199). The time for isolated and infrequent data collection and problem solving regarding a student's program has passed. We must integrate our efforts throughout educational decision making (entrance, performance monitoring, and exit) to maximize impact on the student's educational experiences.

Best Practices in School-Based Behavioral Consultation

Thomas R. Kratochwill
Stephen N. Elliott
Pamela Carrington Rotto
University of Wisconsin–Madison

Consultation has become a major approach for providing psychoeducational services to children and adolescents. The three major models of consultation used most frequently are mental-health, organizational-development, and behavioral consultation, but many more have been identified (see Zins, Kratochwill, & Elliott, 1993). Although differences exist among these models, all emphasize an increase in the problem-solving expertise of the consultee within a triadic relationship (consultant-consultee-child). The behavioral model of consultation has emerged as an alternative to traditional service-delivery approaches in applied settings (Reschly, 1988).

While behavioral consultation traditionally has been affiliated with behavior modification and intervention techniques from this theoretical school (Kazdin, 1989; Sulzer-Azaroff & Mayer, 1977) a more current focus is to use a wide range of intervention technologies from diverse theoretical origins. For example, school psychologists may apply behavioral principles and techniques in developing intervention programs and use behavioral methodologies to evaluate the effectiveness of these services (see Martens, 1994). Likewise, school psychologists also may apply valid instructional principles such as pause time, pacing, teacher feedback, and/or homework instruction when developing an intervention plan to enhance the academic performance of underachieving students. Whereas specific intervention strategies may vary across presenting problems, two identifiable features are most frequently associated with behavioral consultation, namely, indirect service delivery and a problem-solving approach.

The most widely recognized feature of behavioral consultation is its *indirect service* delivery approach (Bergan & Kratochwill, 1990). Services are delivered by a consultant (school psychologist) to a consultee (teacher or parent) who, in turn, provides services to a child in the school or community setting. The indirect approach to service delivery generally is regarded as a distinct advantage of behavioral consultation because it allows the psychologist to impact many more children than could be served by a direct service approach.

Behavioral consultation involves a collaborative relationship in which the consultant is viewed as a facilitator. Emphasis is placed on the collaborative *problem-solving process* which occurs during a series of interviews and related assessment activities. Throughout this process, the psychologist's role is to elicit a description of the problem, assist in analyzing the problem, devise a plan for intervention, and monitor the program once implemented. The teacher's or parent's role is to clearly describe the problem, work with the child to implement the intervention program, observe progress, periodically evaluate the plan's effectiveness, and supervise the child's actions (Elliott & Sheridan, 1992).

BASIC CONSIDERATIONS

Behavioral consultation has two important goals: (a) to provide methods for changing a child's behavioral, academic, or social problem and (b) to improve a consultee's skills so he or she can prevent or respond effectively to future problems or similar problems in other children. Given these goals, behavioral consultation can be both a proactive and a reactive service. Researchers indicate that behavioral consultation often has changed children's problem behaviors successfully (Gresham & Kendell, 1987). However, the more proactive goal of influencing a teacher's or parent's ability to handle future problems has not been observed consistently. The accomplishment of these goals requires consultees to participate in a general process for analyzing problems that results in an effective plan to resolve the problem. Successful behavioral consultants must demonstrate expertise both in coordinating and facilitating the problem-solving process and in behavior change methods. Although competence in problem identification, applied behavior analysis, and plan implementation are necessary conditions of behavioral consultation, they are not sufficient to facilitate effective consultative interactions. Integration of positive interpersonal skills and understanding with technical expertise are equally important to maximize consultant-consultee effectiveness. For example, characteristics such as acceptance through nonjudgmental statements, openness, nondefensiveness, and flexibility positively affect the interaction between consultant and consultee. In the remainder of this chapter, the basic components of problem solving in behavioral consultation, specific consultant-consultee relationship variables influencing the consultation process, and use of consultation with teachers and parents will be discussed.

The Structure and Process of Behavioral Consultation

Behavioral consultation has been conceptualized as a series of stages that structure and focus the problem-solving interaction between a consultant and consultee (Bergan & Kratochwill, 1990). A heuristic four-stage framework for behavioral consultation begins with *problem identification and problem analysis*, progresses to *plan implementation*, and concludes with *plan evaluation*.

Problem identification is the initial and perhaps most critical stage of consultation because it results in the design and implementation of an effective plan. The interview represents the primary assessment technology for defining the problem, although numerous other strategies assist in defining the problem or issue (e.g., tests, rating scales and checklists, direct observations). During the problem identification interview, the consultant and consultee focus on describing and operationally defining the child's behaviors which are of concern to the parent/teacher. In behavioral consultation a "problem" is a relative concept operationalized when the parent/teacher reports a significant discrepancy between the child's current level of performance and the desired level of performance. The determination of whether a significant discrepancy exists is not examined initially; however, once the current and desired levels of performance are defined objectively, this significant discrepancy becomes the focus. This approach to problem identification is based on the assumption that problems are the result of unsuccessful or discrepant interactions between persons (e.g., child and teacher, child and parent). Thus, the psychologist and parent/teacher first analyze the target problem within the ecological context of the child and his/her interactions with the environment. When baseline data support the existence of the specific problem, the psychologist and parent/teacher jointly begin to identify factors that might lead to behavior change and problem resolution.

Problem analysis, the second major stage of behavior consultation, focuses on the variables and conditions that are hypothesized to influence the child's behavior. Problem analysis is a natural extension of the problem identification stage, in that it essentially begins with the target behavior of concern and focuses on establishing functional relationships between it and the antecedent or consequent event. Questions about who, what, where, when, and under what conditions or contingencies all are relevant, and generally facilitate a better understanding of the problem behavior. In many cases, the problem analysis stage will require the psychologist to collect additional data about the child's target behavior. Thus, problem analysis may enhance refinement and, consequently, redefinition of the target problem and the factor(s) which influence it.

Plan implementation follows the problem analysis stage and has the dual objectives of (a) selecting an appropriate intervention and (b) implementing the intervention. Procedural details are essential at this stage, such as assigning individuals to various roles, gathering or preparing specific materials, and/or training individuals to implement the plan. The selection of interventions traditionally seems to have been based on the reported or assumed effectiveness of a particular method. Many consumers and providers of psychological services, however, are demanding that interventions also be acceptable (i.e., time efficient, least restrictive, fair and/or low risk to the target child; Elliott, 1988a, 1988b). Likewise, interventions consistent with the consultee's child-management philosophy and compatible with existing resources and the skills of the individual delivering the intervention also have gained recent consumer interest and empirical support (Witt & Martens, 1988). The design and selection of appropriate interventions should be based on empirically supportable treatments and requires attention to issues of intervention acceptability, intervention effectiveness, and consultee skills and resources. Plan implementation also involves discussing and actually carrying out the selected intervention. This substage may consume several weeks and is characterized by interactions between the parent/teacher and child. These interactions may occur through brief contacts in which the psychologist monitors intervention integrity and side effects (Gresham, 1989), and possibly brainstorms with the parent/teacher ways to revise the plan and its use. The school psychologist's role also may involve observations to monitor child and consultee behaviors or training sessions to enhance the skills of the individual who is executing the treatment plan.

Plan evaluation is the final stage of consultation. The objectives of this stage are to establish a sound basis for interpreting outcomes of the intervention for the targeted problem and to provide a forum for evaluating plan effectiveness. The rigor of evaluation involved in research may not be used in practice, but good evidence to verify outcomes should be routine in case consultation efforts. Single-subject or case study strategies and direct observations, which largely have been adopted as the methodology for applied behavioral psychology, provide one means for evaluating change in the child's behavior. When the reported discrepancy between the child's behavior and desired level of functioning is reduced significantly or eliminated, and the treatment is acceptable to both the teacher/parent and child, the consultant and consultee decide whether consultation should be terminated. Outcome criteria should include maintenance of the desired behavior over time and generalization across multiple settings and conditions. In theory, a consultative case is not concluded until the discrepancy between the child's existing and desired behavior is reduced substantively and an acceptable maintenance plan is in place. Criteria such as overall improvement in the quality of life (social and academic) can also be involved but may require a developmental focus to consultation interactions. Therefore, it often is necessary to recycle through previous stages of consultation and re-evaluate refined or newly implemented interventions.

In summary, behavioral consultation is a model for delivering psychoeducational assessment and intervention services to children via teachers or parents through a series of interviews. A heuristic problem-solving framework and behavioral principles provide structure for collecting information and affecting behavior change. Although the problem-solving structure is sequential and overt, it should not be interpreted as inflexible or irreversible. The activities of consultants and consultees are multifaceted, involving at least interviews, observational assessments, treatment of the target behaviors, and evaluation of the treatments. Such activities generally require several interactions between the consultant and consultee, as well as ongoing consultee and client collaborative interactions.

Consultant-Consultee Relationship

The interpersonal relationship between a psychologist and parent/teacher is assumed to play a major role in the use and effectiveness of behavioral consultation. Thus, as with psychotherapy, issues of trust, genuineness, and openness have been deemed important qualities for both consultants and consultees (Conoley & Conoley, 1982; Martin, 1978). These human qualities are magnified in a consultative model of service delivery due to the predominance of an interview mode of information gathering and sharing. The dynamics of communication, both talking and listening, are the medium through which psychologists display their attitudes about parents and teachers. Personal characteristics, professional competencies, and behavioral principles of reinforcement and modeling all are important elements in establishing and maintaining constructive and professional interactions.

Sensitivity to issues of importance to parents and teachers also contributes to the development of a positive consulting relationship. Variables commonly examined in treatment acceptability research (Elliott, 1988a; Witt & Elliott, 1985) and dimensions of helping emphasized by empowerment theorists (Dunst & Trivette, 1988; Witt & Martens, 1988) can be considered consistent with behavioral consultation because they are relevant to the enhancement of relationships with parents and teachers. Specifically, treatment acceptability researchers repeatedly have found that administration/management time and fairness of the treatment are important themes virtually to all teachers, and nonaversive approaches to intervention are valued highly by most teachers. Work by empowerment theorists applied to consultation suggests that (a) help is more likely to be perceived positively if it is offered proactively, (b) competence within teachers is best promoted by building upon their existing child-management strengths rather than remediating deficits, and (c) use of existing resources in the school environment is preferred over the intervention or purchase of new resources (Witt & Martens, 1988). Thus, it is concluded that effective behavioral consultants (a) overtly communicate awareness of issues central to teachers' daily functioning and (b) act cooperatively to design interventions. Such consultative actions may overcome many potential sources of resistance.

Resistance is a topic of considerable concern to practitioners and researchers alike and often has been conceptualized as something bad which resides within a person or institution. As observed by Wickstrom and Witt (1993), such a view of resistance is overly simplistic and unnecessarily negative. Within the context of a consultant-consultee relationship, they define resistance as "including those system, consultee, consultant, family, and client factors which interfere with the achievement of goals established during consultative interactions . . . [Resistance, then, is] *anything* that impedes problem solving or plan implementation and ultimately problem resolution" (Wickstrom & Witt, 1993, p. 160). This definition stresses that resistance is part of a system context and is multidirectional; that is, it does not reside in only one part of the system.

Behavioral consultation addresses resistance to consultation in terms of situational antecedents and consequences of the consultee's behavior (Bergan, 1985). Having reviewed the theoretical and empirical reports on resistance to treatment in both the psychotherapy and consultation literature, Wickstrom and Witt (1993) recommend two general tactics to responding to resistance. The first tactic they call "Joining the consultee" and the second they refer to as "Emphasizing referent power." Joining the consultee involves understanding a consultee's attribution system for explaining a problem of concern and then using that attributional framework to build a link to an intervention. Emphasizing referent power involves a consultant working to become more similar to a consultee. This tactic can be accomplished by using nonauthoritarian and noncoercive means of control, using cooperative modes of interaction, asking questions, and making suggestions for change tentatively (Parsons & Meyers, 1984). Efforts to use the consultee's existing skills and preferences for interaction activities, thereby reducing the number of "new" aspects of an intervention, also is likely to make suggestions more acceptable, and thus less resisted.

In closing this section, the reader might do well to remember that "once the door to the classroom is closed, there is little that any of the educational specialists can do to insure that occurrence of any event that the teacher does not want to occur" (Gutkin & Curtis, 1981, pp. 220–221). Hence, the interpersonal or therapeutic relationship skills of a psychologist are as important to the delivery of behavioral consultation as knowledge of assessment and intervention methods.

BEST PRACTICES IN THE DELIVERY OF BEHAVIORAL CONSULTATION

As noted in the previous sections of the chapter, behavioral consultation consists of a series of stages or phases used to implement the process of consultation. These stages include problem identification, problem analysis, plan implementation, and plan evaluation. Each of these steps, with the exception of plan implementation, involves a formal interview resulting in specific objectives. Best practices in behavioral consultation suggest that psychologists adhere to specific objectives and activities within each phase. The major components for each of these phases are outlined next.

Problem Identification

Problem identification is achieved through an interview where the primary objectives are to specify the goals, assess the problem, and implement certain procedures. Behavioral consultation can involve a developmental or problem-centered focus. In developmental consultation the consultant establishes general, subordinate, and performance objectives. Usually these are obtained over a long period of time and in several series of interviews. In contrast, problem-centered consultation involves specification of problems that are specific and relate to one primary concern. Relative to the developmental consultation process, problem-centered consultation is time-limited.

Whether the nature of consultation is developmental or problem-centered, the psychologist needs to achieve clear specification of problems. Typically, this process involves generating precise descriptions of the student's behavior, carefully analyzing the conditions under which the problems occur, and establishing some indication of the level of persistence or strength of the problems. Another important objective is establishing an assessment technique. Together, the teacher and/or parent and psychologist agree on the type or kind of measure to be used, what will be recorded, and how this process will be implemented. Finally, certain procedural objectives must be met during the problem-identification phase. One of the first objectives involves establishing times, dates, and formats for subsequent interviews and contacts with the teacher or parent to examine procedural aspects of the consultation process. For example, the psychologist may agree to contact the teacher/parent weekly or biweekly to determine whether data are being gathered properly or if any unique barriers have occurred. Witt and Elliott (1983) outlined nine components that facilitate the problem-identification interview. These components were written as objectives and are briefly described as follows:

1. **Explanation of problem-definition purposes.** The parent or teacher should be told what is to be accomplished during the interview and why problem identification is important. (Example statement: "I would like to talk with you a few minutes about John and his behaviors that bother you most. We will need to assess his behaviors, when and how often they occur, and what factors in your classroom [or home] influence them.")

2. **Identification and selection of target behaviors.** The parent or teacher should be asked to focus attention on the problematic aspects of a student's difficulties. (Example statement: "Please describe exactly what John is doing that has caused you concern.") When individuals identify multiple problems, it is necessary to determine which to address. (Example statement: "Which of these concerns is most pressing to you now?")

3. **Identification of problem frequency, duration, and intensity.** After a target behavior has been defined, it is helpful to assess its basic characteristics: How often does it occur (frequency), how long does it last (duration), and how strong is it (intensity)? (Example statements: "How many times did John cry last week?" "How long does each crying session last?" "Does he cry loud enough for everyone in the room to hear him?") To interpret descriptions of frequency, duration, and intensity, the parent or teacher may be asked to compare the target child's behavior with that of other children. In addition, a psychologist should have knowledge of normative expectations to which the child's behavior can be compared.

4. **Identification of the conditions under which the target behavior occurs.** The assessment of environmental factors that occur in conjunction with a target behavior is essential in understanding

the problem. (Example statement: "How do you and the class react to John's crying?") Use of a simple model of behavior, such as the ABC model, can help unravel many problems. This model construes behavior (B) to be a function of antecedent (A) and/or consequent (C) events. Thus, once a behavior has been identified, a consultant looks at events that chronologically precede and follow it.

5. **Identification of the required level of performance.** Obtaining a description of the behavior required of a student is as important as obtaining a description of the student's problem behavior. (Example statement: "What would you consider to be an acceptable frequency for this out-of-seat behavior?") Once a desired or expected level of performance is identified, it serves as a goal.

6. **Identification of the student's strengths.** Learning what a child does well is often more useful than learning what a child does not do or does poorly. (Example statement: "What does John do best when interacting with his classmates?") Developing interventions that use a student's strengths helps to increase the probability of a successful treatment.

7. **Identification of behavioral assessment procedures.** All interventions require some assessment or recording of behavior. Thus, a consultant should help a teacher or parent decide what, how, when, and where behavior will be recorded and who will do the recording.

8. **Identification of consultee effectiveness.** Given that one major goal of behavioral consultation is to enable a consultee to solve his or her own problems in the future, it may be necessary to teach or model problem-solving skills and enhance the consultee's confidence in his or her ability to solve problems. The goal obviously is for the consultant to be helpful to the consultee. To accomplish this goal, Witt and Martens (1988) advocate an empowerment, rather than an advice-giving, philosophy of service for consultation. However, an empowerment philosophy assumes consultees basically are skilled individuals who can become more capable of solving their own problems by knowing what resources are available and how to gain access to them (Dunst & Trivette, 1988). If the consultee does not have the skills to provide services to the client, these skills should be taught or other treatment options considered. One can determine the consultee's potential effectiveness by asking about how similar problems have been handled in the past, assessing what methods the consultee already has used to remediate the target problem, and judging whether the consultee is self-reliant or dependent on others for reinforcement (Meyers, Liddell, & Lyons, 1977).

9. **Summary of the interview.** The final step in the problem identification stage should include a summary of the important points discussed and a review of the problem definition. This summary should include a statement of the specific target behavior(s) or clarification of any further assessment necessary to refine the target behavior(s).

Specific objectives associated with the consultation problem-identification interview are presented in Table 1. These are general objectives that need to be established in the consultation interview but typically correspond to features of the Consultation Analysis Record (see Bergan & Kratochwill, 1990).

Problem Analysis

After baseline data are collected on the areas of concern, the psychologist and teacher/parent meet to decide jointly on factors that might lead to some resolution of the problem. In this regard, the consultation process will focus on student, parent/teacher, and general environmental variables that may be of relevance.

The problem analysis interview includes five major steps: (a) choosing analysis procedures, (b) determining the conditions and/or skills analysis, (c) developing plan strategies, (d) developing plan tactics, and (e) establishing procedures to evaluate performance during implementation of any treatment program. Within the context of these phases, the psychologist might first analyze the factors that lead to potential solution of the problem and then develop a plan to solve the problem.

The psychologist focuses on conditions that facilitate attainment of the mutually agreed upon goals. Generally, it is necessary to accomplish the following:

1. Specify whether the goal of treatment is to increase, decrease, or maintain behavior.

2. Identify setting events and antecedent/consequential conditions associated with behavior.

3. Determine which current conditions affect the behavior by comparing the existing situation to related research findings.

4. Identify conditions not currently associated with behavior but which nonetheless could influence solving the problem.

During the problem analysis phase, the psychologist and teacher/parent, through mutual problem-solving efforts, must analyze the kinds of child skills necessary to achieve the consultation goals. Analysis of the child's skills can include both academic and social performance. Basically, the psychologist must work with the teacher/parent (and child if possible) to identify psychological and educational principles that relate to attaining the consultation goals. It is beyond the scope of this chapter to outline these procedures in great detail. Rather, the reader is referred to a number of sources that can be useful to analyze

TABLE 1
Problem Identification Behavior

Behavior Specification

Definition: The consultant should elicit behavioral descriptions of client functioning. Focus is on specific behaviors of the child interms that can be understood by an independent behavior. Provide as many examples of the behavior problem as possible (e.g., What does Cathy do?).

a. Specify behavior:

b. Specify examples of the problem behavior:

c. Which behavior causes the most difficulty? (i.e., prioritize the probelms from most to least severe):

Behavior Setting

Definition: A precise description of the settings in which the probelm behaviors occur (e.g., Where does John do this?).

a. Specify examples of where the behavior occurs:

b. Specify priorities (i.e., Which setting is causing the most difficulty?):

Identification of Antecedents

Definition: Events which precede the child's behavior. Provide information regarding what happens immediately before the problem behavior occurs (e.g., What happens right before Kristy hits other children?).

Sequential Conditions Analysis

Definition: Situational events occurring when the problem behavior occurs. Environmental conditions in operation when it occurs. For example, time of day or day of week when the problem behavior typically occurs. Sequential conditions are also defined as the patter or trend of antecedent and/or consequent conditions across a series of occasions (e.g., What is happening when the behavior occurs?).

Identification of Consequent Conditions

Definition: Events which occur immediately following the client behavior (e.g., What happens after the problem behavior has occurred?).

Behavior Strength

Definition: Indicate how often (frequency) or how long (duration) the behavior occurs. Behavior strength refers to the level or incidence of the behavior that is to be focused on. The question format used for each particular behavior strength will depend upon the specific type of behavior problem (e.g., How often does Shelly have tantrums? or How long do Brett's tantrums last?).

a. Frequency of behavior:

b. Duration of behavior:

Tentative-Definition-of-Goal Question

Definition: Appropriate or acceptable level of the behavior (e.g., How frequently could Matthew leave his seat without causing problems?).

Assets Question

Definition: Strengths, abilities, or other positive features of the child (e.g., What does Jane do well?).

Approach to Teaching or Existing Procedures

Definition: Procedures or rules in force which are external to the child and to the behavior (e.g., How long are Sue and other students doing seat-work problems?).

Data-Collection Procedures

Definition: Specify the target responses to record. This recording should include the kind of measure, what is to be recorded, and how to record. Specific details of data recording should be emphasized.

Date to Begin Data Collection

Definition: Procedural details of when to begin collecting baseline data.

overt behavioral and cognitive features relating to instructional and social functioning (e.g., Bergan & Kratochwill, 1990; Kazdin, 1989; Kratochwill & Morris, 1992).

The outcome of successful problem analysis is a plan to put into effect during the treatment implementation process. Development of this plan should begin with specifying broad strategies that can be used to achieve the mutually agreed upon goals. The plan typically includes *sources of action* to be implemented. Secondly, plan tactics are used to guide implementation of the strategy and outline principles to be applied during the intervention. For example, if reinforcement strategies are to be used, the person responsible for carrying out the plan and the conditions under which they will occur should be specified. During this phase psychologists might also assess treatment acceptability prior to its implementation. A number of scales have been developed for assessment of pretreatment acceptability and readers are encouraged to consult this material (Elliott, 1988b; Witt & Elliott, 1985). Appendix A is a sample rating scale that can be used in assessing treatment acceptability.

Finally, during problem analysis the psychologist and teacher/parent must establish performance and assessment objectives that will be used during plan implementation. Typically this procedure follows from a conditions analysis and involves specification of an assessment procedure previously used during baseline. For example, when plan implementation involves skill development, some agreed upon format for collection of data on performance related to the final objectives achieved is necessary.

Table 2 provides an example of the general objectives that should be met during the problem analysis interview. These objectives generally involve validating the problem, analyzing the problem and related variables, designing the plan, and developing the procedural goals.

Plan Implementation

The third stage in behavioral consultation involves implementing a treatment plan. Some initial activities are necessary to enhance the likelihood of intervention success. In this regard, the psychologist should maximize the probability that the intervention plan is put into effect by the teacher/parent and/or child during this part of the consultation process. This step will require collaborative decisions regarding role assignments, material assembly, and skill development, as needed during the process. Although there is no formal interview during the plan implementation phase, it is the responsibility of the psychologist to monitor the implementation of the intervention and work with the teacher/parent to revise procedures during plan implementation, if it is deemed necessary. It also may be desirable for the consultant to observe the child and/or teacher or parent to monitor behaviors and determine the need for subsequent revisions in the plan.

During plan implementation the three major tasks that must be accomplished include skill development of the consultee (if necessary), monitoring the implementation process, and plan revisions. Typically, the psychologist must determine whether the teacher/parent has the skills to carry out the plan. If skill development is required, the consultee must be offered some type of training or guidance.

The second task, to monitor data, can determine if assessment is occurring as intended. Usually consultee records are examined to assess child outcome. This process indicates to the school psychologist when data are being gathered, how the performance of the child is being assessed, and what behaviors are being observed. It may also help the psychologist determine whether the plan is actually proceeding as designed. If little progress is observed, then it is advisable for the school psychologist to meet with the teacher/parent and revise the plan accordingly.

Monitoring plan implementation generally occurs in two ways. First, the child's behavior is monitored on an ongoing basis by the teacher/parent. This monitoring is a continuation from the problem identification and problem analysis phases of consultation. A second type of monitoring activity involves an evaluation of the strategies associated with the plan implementation itself. It is essential for the psychologist and teacher/parent to ensure that the plan agreed upon is being carried out as designed. The psychologist may monitor plan implementation and integrity by discussing the intervention plan with the teacher or parent, and, to complement this strategy, actually observe the plan in operation or to get the consultee to report integrity data periodically (Gresham, 1989). Although various individuals might serve in the role of treatment implementors, it is nonetheless likely that the agreed upon procedures to facilitate plan implementation are compatible with the resources and responsibilities of the school setting.

Finally, changes should be made in the plan when necessary. If the child's behavior is not changing in the desired direction, plan revision should occur. Generally, this outcome will require that the psychologist and teacher/parent return to the problem analysis phase to further analyze variables such as the setting, intrapersonal child characteristics, or skill deficits. Likewise, it may be necessary to return to the problem identification stage if it is determined that the nature of the problem has changed.

Plan Evaluation

Plan evaluation is implemented through a formal plan evaluation interview and typically is undertaken to determine whether the consultation goals have been reached. The process of evaluation includes as-

TABLE 2
Problem Analysis Interview

Strength of Behavior

Definition: Question or statement regarding behaviors, specific to the baseline data collected (e.g., It looks like Karen refused to do the assigned work except on Tuesday.).

Antecedent, Consequent, and Sequential Conditions

a. *Antecedent:* Events which precede the child's behavior. Information regarding what happens immediately preceding the problem behavior (e.g., Did you notice anything in particular that happened just *before* ...).

b. *Consequent:* Events which occur immediately following the child's behavior (e.g., What happened *after* Mary ...).

c. *Sequential:* Situational events or environmental conditions in operation when problem behavior occurs. Pattern or trend of conditions across occurrences such as day of week, time of day, etc. (e.g., What was happening *when* Jimmy ...).

Interpretation of Behavior

Definition: Consultant elicits the consultee's perception regarding the purpose of function of the behavior (e.g., Why do you think Justin is so disrespectful?).

Establishing a Plan

Definition: Consultant and consultee establish plan strategies and specific targets that might be used in treatment implementation. Consultant may ask for or provide strategies (e.g, What could be done to change the setting in which Charles gets into fights? OR We need to try something different. What could be done before Ron makes the abusive remarks?).

Continuation of Recording Procedure

Definitiona; Establish recording procedures to be used in treatment plan implementation.

---

sessment of goal attainment, plan effectiveness, and implementation planning.

Deciding whether the actual goals previously agreed upon have been met is determined through discussion with the consultee and observation of the client's behavior. The process of evaluating goal attainment was initiated during the problem-identification stage when the objectives and procedures for measuring mastery were specified. The data gathered since that phase should provide some evidence as to whether there is congruence between objectives and the problem solution. This congruence is essentially determined on the basis of the data collected; however, additional strategies, such as social validation criteria, might also be invoked. That is, the school psychologist will want to know whether the child reached some clinically established level of change and whether the intervention program brought the child's performance within a range of acceptable behavior as compared to normal or typical peers. Determination of the congruence between behavior and objectives generally leads the psychologist to conclude that no progress was evident, some progress was made, or the actual goal was obtained.

The mechanism for evaluating plan effectiveness can occur through one of several case-study strategies that have been used frequently in applied behavior analysis or single-case research. In this regard, a variety of clinical experimental procedures might be implemented to facilitate decisions regarding progress in the consultation process. Again, it is beyond the scope of this chapter to outline these in great detail. Instead, the interested reader is referred to a primary source where these designs are reviewed (e.g., Barlow, Hayes, & Nelson, 1984). The recommended strategies basically involve a simple time-series design which includes an A/B format. Recent work by Busse, Kratochwill, and Elliott (in press) summarizes strategies for interpreting time-series data for consultation outcomes.

Advances in the evaluation of treatment effects and consultation outcomes continue to appear in the research literature. Several of these advances have been used in the evaluation of community mental health services and supplement the case-study and social-validation strategies traditionally used by consultants. Two of the most practical strategies are Goal Attainment Scaling (GAS; Lloyd, 1983) and the Reliable Change Index (RC; Gresham, in press; Jacobson, Follette, & Revenstorf, 1984).

Briefly, there are several different approaches to GAS. The basic tactic, however, is one where a consultee would be asked to describe five levels of treatment outcome. The most unfavorable outcome described is given a –rating, the expected outcome a 0 rating, and the most favorable outcome a +2 rating. Ratings of –1 and +1 are ascribed to descriptions of outcomes situated between the most unfavorable and expected outcome and the most favorable and expected outcome, respectively. This system of rating treatment outcomes can be used to get weekly measures on treatment progress, as well as final outcome perceptions from a consultee. GAS is a sensitive system because both over- and under-attainment of objectives can be rated. Both Lloyd (1983) and Rinn, Vernon, and Wise (1975) have developed GAS statistics to allow for comparisons across subjects.

The RC evaluation method was first proposed by Nunnally and Kotsche (1983). RC is defined as the difference between posttest scores and pretest scores divided by the standard error of measurement. Typically an RC of + 1.96 or greater is considered statistically significant, and more importantly it is inferred that the intervention produced a reliable change in a person's behavior. The RC is designed to be used with data from rating scales or individualized tests where total pretest and posttest scores can be calculated. Be cognizant, however, that this metric for reporting treatment outcomes is affected by the reliability of the dependent measures. Gresham (1991) noted that the dual criteria of social validation (social comparison and subjective evaluation) and RC should provide practitioners with a means for documenting educationally and statistically significant changes in behavior.

Once it has been determined that the problem has been solved, post-implementation planning occurs to help ensure that the particular problem does not occur again. This planning by the psychologist and teacher/parent can take several forms. One strategy is to leave the plan in effect. Typically, however, a plan that is put into effect will need to be modified (another strategy) to facilitate maintenance of behavior over time. There is considerable evidence in the treatment literature that specific tactics are needed to facilitate maintenance and generalization of behavior and these tactics must be accomplished during this phase of consultation. Generalization may occur naturally, but more likely it will need to be programmed. Several factors have been identified that have a bearing on the generalization of skills (Haring, 1988; White et al., 1988). Table 3 from White et al. (1988) lists the strategies for facilitating generalization along with a definition and example. The table is based on the seminal work of Stokes and Baer (1977) and can serve as a useful guideline for consultants.

Another major objective that should occur during the plan evaluation interview is discussion of post-implementation recording. Generally, this procedure refers to the process of continuing record-keeping activities to determine whether the problem reoccurs in the future. To facilitate this data collection process, the school psychologist and teacher/parent usually select periodic measures that are convenient to use and may maintain specific features of the original plan. Best practices also suggest that the psychologist consider conducting post-plan implementation acceptability assessment as well. These procedures can be implemented informally or more formally with acceptability instrumentation (Elliott, 1988b).

Finally, the teacher/parent should notify the school psychologist of any indications that the problem behaviors might be reoccurring. These usually can be brought to the psychologist's attention and specific tactics set up to establish a system to analyze the problems. Table 4 provides an overview of the general objectives of the plan evaluation interview.

USE OF BEHAVIORAL CONSULTATION WITH TEACHERS AND PARENTS

Traditionally, school psychologists have implemented consultation with classroom teachers in an effort to establish intervention programs in the regular classroom and thereby reduce the number of placements in special education programs. This emphasis on prevention and direct intervention with teachers advanced the development of a knowledge base to prevent more serious behavioral problems in children. Within the past decade, school-based consultation services have expanded to include work with special education teachers, particularly teachers of emotionally impaired children (Kratochwill, Sheridan, Carrington Rotto, & Salmon, 1991) and teachers from early intervention programs for preschool-age children (Kratochwill & Elliott, 1993). In addition, behavioral consultation also has been used successfully to remediate academic and socialization difficulties in school settings. Applications such as these have presented unique opportunities for school psychologists to increase contact with special education teachers while generally addressing more severe presenting problems in special needs children who often experience multiple difficulties. Hence, the role of consultation has become increasingly specialized, with unique time demands and treatment needs which may vary according to the child's presenting problems and the teacher's level of expertise in areas such as behavior management and individualized instruction.

Although behavioral consultation with teachers is an effective method of remediating school-based problems, this focus fails to address the broader context within which the child's problems may occur. For example, a withdrawn child who exhibits an absence of peer interactions at school likely would be unable to develop and maintain positive social relationships with neighborhood peers. Focusing exclusively on this child's social withdrawal in the school setting through teacher-only consultation restricts conceptualizations, analysis, and treatment of the problem to a single setting. The broader behavioral interrelationships across environments would not be considered. However, behavioral consultation has been extended to serve as a link among the significant settings in a child's life, primarily, the home, school, and commu-

TABLE 3
Strategies for Facilitating Generalization

Strategy	Definition	Example
Train & Hope	Providing simple instruction and then "hoping" that generalization will occur. Actually the *absence* of any special strategy.	Three preschool boys who were blind and severely or profoundly retarded were taught to reach for noise-making toys always presented at the midline. None of the boys generalized to objects presented on the right or left.
Setting		
Training in the Natural Setting	Training is conducted directly in at least one type of setting in which the skill will be used. Generalization is then probed in other non-training setting.	The social interaction skills of several individuals with severe handicaps were trained in the classroom and courtyard during class breaks.
Sequential Modification	Training is provided in one setting, and generalization is probed in other settings. If necessary, training is conducted sequentially in more and more settings until generalization to all desired settings is observed.	One girl with moderate handicaps needed articulation training in 3 settings before generalizing to all remaining situations of interest; a second girl only required training in two situations before generalizing.
Consequences		
Introduce to Natural Maintaining Contingencies	Ensuring that learner experiences the natural consequences of a behavior by: (1) teaching a functional skill which is likely to be reinforced outside instruction; (2) training to a level of proficiency that makes the skill truly useful; (3) making sure that learner actually does experience the natural consequence; and/or (4) teaching the learner to solicit or recruit reinforcement outside instruction.*	Three teens who were multiply handicapped and severely retarded were taught to use symbols & pictures to request objects. Generalization was encouraged by using objects which would be regularly encountered outside instruction, making sure the boys always carried their communication boards, and that someone would always be present to provide any requested items.
Use Indiscriminable Contingencies	If natural consequences cannot be expected to encourage and maintain generalization, atificial consequences or schedules of natural consequences might be used. However, it is best if the learner cannot determine precisely when those consequences will be available, and so must behave as if they always are.	Two behavior disordered and five normal preschool children always generalized their interaction and study better when verbal praise by the teacher was provided after progressively greater delays, rather than immediately following each behavior.
Train to Generalize	The learner is only reinforced for performing some generalized instance of the target skill. Performing a previously reinforced version of the response is no longer reinforced.	Four youths with severe retardation were taught to name specific items. Contingencies were then altered so they were only reinforced if they named *untrained* items. After 3 sessions, all youths generalized well to untrained items.
Antecedents		
Program Common Stimuli	Selecting a salient, but not necessarily task-related, stimulus from the situation to which generalization is desired, and including that stimulus in the training program.	Stokes & Baer (1977) report a case in which an individual with severe retardation was taught exercise skills to facilitate integration in a physical education class. Music was played during the PE class, so music was also introduced into the individual's training sessions to make the two situations more similar.

(Table 3, continued)

Sufficient Exemplars	A strategy similar to Sequential Modification, involving sequential addition of stimuli to the training program until generalization to all related stimuli occurs.[2]	An adolescent with severe handicaps was taught to name objects, and probed with other objects from the same class. Some objects required only a single exemplar to produce generalized naming, while other objects required 5 exemeplars before generalization occurred.
Multiple Exemplars	Several examples of the stimulus class to which generalization is desired are trained at the same time.	Three adults with profound mental retardation were trained in three types of exercise. Generalization occurred to a group exercise program and to two untrained exercises.,
General Case Programming	The universe to which generalization is desired is analyzed and representative examples of positive stimuli (stimuli in the presence of which the skill should be used), negative stimuli (stimuli in the presence of which the skill should not be used), and irrelevant stimuli (stimuli which should not effect skill use, but might inappropriately do so) are selected for training.	Six young men with moderate to severe retardation were trained on three vending machines which reflected the range of machine-types found in community. Good generalization was obtained to 10 untrained machines in the community.
Other		
Train Loosely	Settings, cues, prompts, materials, response definition, and other features of the training situation are purposely varied to avoid a ritual, highly structured, invariate program which might inhibit generalization.	Mothers were taught to vary the type of stimuli and reinforcers they used in working with their children's motor skills. All children learned their skills quickly and generalized well to another setting.
Mediate Generalization	Teaching a secondary behavior or strategy which will help an individual remember or figure out how and when to generalize, or which will dispel the differences between the training and generalization situations.	Five adolescents with moderate or severe mental retardation were taught to self-instruct task completion using a picture sequence. They then used the self-instruction skill to generalize task completion of a new task with a new picture sequence.

[1] Stokes and Baer (1977) described this strategy as training in one situation and, if that fails to produce generalization, training in all remaining situations of interest. The more literally "sequential" nature of the procedure as described above seems better suited for describing current application of the strategy.

[2] Stokes and Baer used this label to describe the successive introduction of new stimuli or settings, but separating the two variations seemed more advisable for the current study (see note 2, above).

Note. From "Review and Analysis of Strategies for Generalization: by White et al., 1978. In N. R. Haring (Ed.), *Generalization for students with severe handicaps: Strategies and solutions* (pp. 15–51). Seattle: University of Washington. Copyright 1978 by the University of Washington. Reprinted by permission.

nity environments. This approach facilitates a comprehensive conceptualization of the problem while involving primary caretakers in the intervention process. In addition, although few investigators have assessed the generalization of treatment effects across settings, the potential benefits of broadening the focus of behavioral consultation to encompass the interacting system in the child's life are apparent.

One method of expanding behavioral consultation services beyond the school setting entails involvement or parent–teacher pairs. In conjoint consultation, parents and teachers together serve as consultees (Sheridan & Kratochwill, 1992; Sheridan, Kratochwill, & Bergan, in press). The primary goals of this approach are to bridge the gap between home and school settings, maximize positive treatment effects within and across settings, and promote generalization of treatment effects over time. Continuous data collection and consistent programming across settings also are inherent with this approach. Conjoint behavioral consultation has been found to be an effective method of service-delivery in enhancing social initiation behaviors across home and school settings (Sheridan, Kratochwill, & Elliott, 1990) as well as increasing the academic productivity of underachieving students (Galloway & Sheridan, 1992) and

TABLE 4
Plan Evaluation Interview

Goal Attainment
Definition: Determine specifically if the goals of consultation have been attained. Question treatment outcome (e.g., How did things go?).

Plan Effectiveness
Definition: Determine the effectiveness of the plan for the specific child. Was the specific plan effective in producing behavior change? What was the internal validity of the plan? (e.g., Would you say that the contract procedure was responsible for reducing John's profane language?).

External Validity of Plan
Definition: Determine the effectiveness of the plan for another child who has a similar problem (e.g., Do you think this plan would have worked with another student?).

Post-Implementation Planning
Definition: Decision is made regarding the advisability of leaving the plan in effect, removing the plan, or constructing a new plan. Selection of a post-treatment alternative may be made (e.g., Do you want to leave the point system in effect for another week to see if Bob's progress continues?).

Plan Modification
Devinition: Establish new plan strategies to increase plan effectiveness. Consultant may suggest a change or question the need for change (e.g., How could we change the reinforcement procedure to make the plan more effective?).

Procedures to Facilitate Generalization and Maintenance
Definition: Procedures to encourage continued progress. Goal is to encourage generalization to other settings, or maintain behavior over a long period of time (e.g., What procedures can be implemented to be sure that Sally continues to finish her homework?).

Follow-Up Assessment
Definition: Discussion regarding follow-up recording procedures to monitor the behavior over time (e.g., Now that we have success in the program for George, how can we monitor his progress in the future?).

decreasing the irrational fears of a kindergarten student (Sheridan & Colton, in press). It also has been used to enhance the effects of parent training in managing the behavior of children diagnosed with attention deficit hyperactivity disorder (ADHD) across home and school settings (Johnson & Tilly, 1993).

Use of behavioral consultation has been extended beyond the schools to address problems with individuals other than teachers, such as parents. Parent-only consultation may be applicable when a child's problematic behaviors are observed predominantly in the home and/or community settings with little evidence of them in the school environment. For example, parent consultation has been used to decrease the noncompliant behaviors of school-age children whose difficult behaviors were displayed at home and in public places but were not observed in the more structured classroom setting (Carrington Rotto & Kratochwill, in press). In addition, behavioral consultation with parents has been advanced as a model of early intervention with the goal of decreasing noncompliant and aggressive behaviors of preschool-age children (Carrington Rotto & Kratochwill, 1993). In parent-only consultation, the traditional behavioral consultation framework provides structure for involving the parent(s) in the process of identifying and analyzing the problem, as well as observing and evaluating treatment effects over time. Use of behavioral technology consultation (i.e., parent training) provides structure for teaching parents specific skills which enhance plan implementation. Necessary preparations for plan implementation include teaching parents specific behavior management skills and ensuring that they are adept at implementing these skills. Further research is needed to examine specific methods of promoting generalization fo parent behaviors (i.e., skill implementation) across settings and situations to enhance specific child behaviors.

In sum, behavioral consultation provides a useful framework for working within and between family and school systems. This systematic problem-solving approach may be conducted with teachers, parents, or teacher-parent pairs to enhance child functioning across home, school, and community settings. Together with parents and teachers, school psychologists may develop and implement intervention plans to address diverse target problems in areas such as academic productivity, socialization, and behavioral difficulties. Future research should be directed toward replication of treatment effects with diverse subject populations and further examination of alternative parent and teacher roles and levels of involvement in consultation.

WRITING BEHAVIORAL CONSULTATION CASE REPORTS

At various times during the course of consultation, the consultant may wish to formally communicate the results of the intervention program to the parent and/or teacher. Indeed, it is the ethical and professional responsibility of the consultant to ensure that information concerning an intervention is communicated in a valid, clear, and concise manner. Although a variety of traditional report formats exist (see Gelfand & Hartmann, 1983; Martin, 1973; Ownby, 1987; for overviews), the present format provides a conceptual scheme for reporting interventions compatible with best practices in consultation. The consultant, however, is advised to modify this format to accommodate personal preferences and meet specific, institutional needs and standards. The reporting format that we present can readily be used for consultation activities that are part of a prereferral intervention or for specialized programs that are part of multidisciplinary team follow-up activities.

The present report format represents an outline for describing the activities of an entire consultation program (see Table 5). Psychologists reporting information prior of completion of the plan would find only parts of this report appropriate. General characteristics of the behavioral consultation report include (a) Background Information, (b) Problem Definition, (c) Intervention Plan, (d) Plan Evaluation, and (e) Summary and Recommendations.

The section on *Background Information* includes demographic information describing the child and details regarding the setting in which the problem occurs. For example, the child's name, date of birth, age, gender, school, parents, address, telephone, and teacher should be specified. The consultant should also include a description of the family, siblings, socioeconomic status, peers, teacher, and any other ecological features relevant to the case.

Many alternative ways exist to define a problematic situation. For example, problem behaviors may be described at various levels of specificity. Alternatively, a problem situation can be conceptualized in terms of reducing negative behaviors or increasing positive behaviors. The purpose of the *Problem Definition* is to provide a description and rationale for the problem as defined by the school psychologist (i.e., consultant) and teacher/parent during consultation. Information from the problem identification interview will be especially relevant. More specifically, details regarding the referral problem, target behavior(s), desired outcome behavior(s), critical setting or situations for change, and a preliminary analysis should be included.

Discussion of the initial referral issue should indicate the referral source and a description of the problem. The consultant also should note that consent for participation was obtained from the child's parents. An operational definition of the problem as agreed upon by the school psychologist and teacher/parent should be described in terms of deficits, excesses, frequency, intensity, and duration. Specifications of the target area(s) and a statement regarding desired outcome(s) also should be included. In addition, the consultant should discuss the critical setting where the child's behavior was expected to change and provide a detailed description of the situations necessary for such a change. Finally, a preliminary functional analysis should compare the antecedents and consequences surrounding the problem behavior to those necessary for attainment of the desired behavior.

The *Problem Analysis* discussion should be based on assessment procedures such as interview, direct observation, and/or standardized scales. Hence, the consultant integrates the baseline data, observational data, and problem identification interview to analyze the discrepancy between the existing behavior and desired behavior. A sample of each observational data sheet used during the case may be included in the report.

A description of any intervention programs or procedures implemented during the process of consultation should be included in the section entitled *Intervention Plan*. The consultant should characterize the basic design of the plan according to variables such as the (a) time needed for implementation, (b) contingencies, (c) criterion for delivery of contingencies, (d) setting and time, and (e) resources or materials. In addition, the consultant should specify clearly the procedures used for promoting new behaviors, increasing existing behaviors, and/or reducing interfering problem behaviors. A rationale describing why the particular intervention procedure(s) are relevant to the target problem is essential. In some cases, a treatment "package" consisting of many specific techniques (e.g., feedback, reinforcement, modeling) may be used. Identification of the individuals who are responsible for implementing the plan and a discussion of the degree to which the plan is acceptable to the teacher/parent and child also should be included. Finally, it is desirable to document the strategies used to facilitate generalization and to verify the intervention plan was implemented as intended.

This list is intended to serve as a resource and should be considered carefully. The consultant must determine the variables most pertinent to the specific case; thus, it may be necessary to generate additional dimensions that adequately describe the intervention. Likewise, some of the intervention variables listed may not apply to all cases. It may be helpful to use headings or an outline format similar to that in Table

TABLE 5

5 to facilitate notetaking during consultation interviews and post-treatment preparation of a clear and concise report.

A complete description of the *Intervention Evaluation Plan* should be provided, including methods used to evaluate the specific treatment components and document changes in the child's behavior. Especially relevant will be data from the plan evaluation interview. The school psychologist should present the results of the program in the context of the data collected over the duration of the program and during the generalization or follow-up phases. For example, direct observations and ratings of the child's performance may provide documentation of intervention outcome. In addition, the consultant may evaluate the performance of a mainstreamed peer for comparison before and after the plan is initiated. At least one figure should be used to portray the data collected, and the school psychologist should acknowledge any unique features of the data (e.g., absence, program not followed) or challenges that may have occurred. The consultant should also provide details regarding any side effects which may have resulted from the intervention plan.

The *Summary and Recommendations* should begin with a brief overview of the results obtained and a rationale for program effectiveness or failure. The consultant also should include suggestions for increasing the effectiveness of the program. Recommendations may provide suggestions for (a) future follow-up, (b) enhancing maintenance/generalization, and (c) subsequent intervention plans. These suggestions should identify the involved socialization agents (e.g., parents, teachers, peers) and relevant materials that may be useful for the child or treatment personnel in future work.

SUMMARY AND CONCLUSIONS

Behavioral consultation is a four stage problem solving approach that uses behavioral technology as the basis for problem identification, analysis, intervention, and evaluation. The major features of behavioral consultation include its indirect service-delivery approach and problem-solving activity.

Behavioral consultation has two principal goals. The first goal is to produce change in the child's behavior indirectly through collaborative problem solving between a consultant (school psychologist) and consultee(s) (teacher/parent). A second, yet equally important, goal of behavioral consultation is to provide knowledge and skills that facilitate teacher/parent effectiveness with similar problems in the future. Behavioral consultation generally is recognized as a series of four stages that are used to implement the process of consultation (Bergan & Kratochwill, 1990). These include problem identification, problem analysis, plan implementation, and plan evaluation. Each of these steps, with the exception of plan implementation, is accompanied by a formal interview process and specific objectives.

Research and practice in behavioral consultation have expanded rapidly. Recent interest in consultative methods as they impact the delivery of psychological services in the schools has resulted in increased attention to this area in the literature. This growing enthusiasm over the potential benefits of behavioral consultation is apparent in the numerous articles on the topic published recently in both the psychological and educational literature (Zins, Kratochwill, & Elliott, 1993). As school psychologists have become interested in the integration of behavioral consultation with daily activities and child adjustment in schools and homes, questions regarding the process and outcome of consultation have surfaced. Studies have examined the application of behavioral principles in consultation to achieve changes in behavior and compared the effectiveness of behavioral consultation to other forms of service delivery.

Research documenting the effectiveness of behavioral consultation has been organized around four areas of investigation: (a) outcome research, (b) process research, (c) practitioner research, and (d) training research (Gresham & Kendell, 1987). Research addressing outcomes of behavioral consultation document its effectiveness in remediating academic and behavior problems manifested by children and youths in school settings (Bergan & Kratochwill, 1990). Likewise, these same studies suggest that changes result in the teacher's and parent's behavior, knowledge, attitudes, and perceptions. Although behavioral consultation traditionally has been directed toward a single client (i.e., teacher), it also has been applied successfully with parent groups.

Typically, much of the process research has focused on problem identification, since the consultant's ability to elicit a clear description of the problem has been identified as the best predictor of plan implementation and problem solution (Bergan & Tombari, 1975, 1976). Studies in this area also have focused on comparing behavioral consultation effectiveness with other forms of service delivery (Medway, 1979). It remains difficult to draw conclusions from the studies addressing variables associated with the process of consultation due to limitations in scope, theoretical base, and research methodology (Gresham & Kendall, 1987).

Studies on practitioner utilization have suggested that school-based consultation is a preferred activity for school psychologists (Gutkin & Curtis, 1981, 1990; Meacham & Peckam, 1978). Likewise, teachers and administrators view consultation as an essential aspect of school psychological services (Curtis & Zins, 1981). However, many practitioners identify limitations in actually implementing consultation due to time constraints and lack of consultee commitment (Gresham & Kendell, 1987).

Overall, behavioral consultation is a rapidly growing area with increasing empirical support. However, future studies must utilize more sophisticated designs and measurement strategies to evaluate variables in consultation. Careful scrutiny of behavioral consultation will impact its future use as an alternative to traditional assessment and intervention practices in educational settings and may result in an increased emphasis on the development of formalized training in school psychology programs. In turn, these developments would contribute to the practice of school psychology and positively impact the children, teachers, and parents receiving psychological and educational services.

AUTHOR NOTES

Preparation of this chapter was supported, in part, by Grant #G008730051 to the first author, Grant #H029F80013 to the second authors, and Grant #H023B10023 to the first and third authors, all from the U.S. Department of Education, Office of Special Education and Rehabilitative Services. The content of the chapter does not represent the views of the U.S. Department of Education.

ANNOTATED BIBLIOGRAPHY

Barlow, D. H., Hayes, S. C., & Nelson, R. O. (1984). *The scientist-practitioner: Research and accountability in clinical and educational settings.* New York: Pergamon Press.
The authors outline specific assessment and measurement strategies that can be used in consultation. The text is especially useful in outlining assessment strategies and case-study techniques that can be helpful during the treatment implementation and treatment monitoring phase of behavioral consultation.

Bergan, J. R., & Kratochwill, T. R. (1990). *Behavioral consultation in applied settings.* New York: Plenum Press.
The authors provide an extensive overview of behavioral consultation research and practice. The text provides detailed information for researchers and practitioners in the conduct of behavioral consultation and accompanied by a companion self-instructional guide (see Kratochwill & Bergan, 1990, which follows).
Kazdin, A. E. (1989). *Behavior modification in applied settings* (revised ed.). Homewood, IL: The Dorsey Press.
The author presents an overview of behavior modification techniques in applied settings. It is extremely useful in consultation because it includes material directly relevant to implementing treatments in applied settings.

Kratochwill, T. R., & Bergan, J. R. (1990). *Behavioral consultation in applied settings: An individual guide.* New York: Plenum Press.
The authors present a practitioner guidebook devoted to behavioral consultation in applied settings. It details the problem identification, problem analysis, treatment implementation, and treatment evaluation phases of behavioral consultation. Specific formats for interviews are provided within the text.

Kratochwill, T. R., & Morris, R. J. (Eds.). (1992). The practice of child therapy (2nd ed.). Boston: Allyn & Bacon.
The editors provide an overview of various treatment approaches that is organized by the major childhood disorders. Although many of the treatments described are used in a direct therapy application, numerous approaches can be used by consultation mediators, especially with training.

APPENDIX A
Behavior Intervention Rating Scale

You have just read abut a child with a classroom problem and a description of an intervention for improving the problem. Please evaluate the intervention by circling the number which best describes *your* agreement or disagreement with each statement. *You must* answer each question.

	Strongly Disagree	Disagree	Slightly Disagree	Agree	Strongly Agree
1. This would be an acceptable intervention for the child's problem behavior.	1	2	3	4	5
2. Most teachers would find this intervention appropriate for behavior problems in addition to the one described.	1	2	3	4	5
3. The intervention should prove effective in changing the child's problem behavior.	1	2	3	4	5
4. I would suggest the use of this intervention to other teachers.	1	2	3	4	5
5. The child's behavior problem is severe enough to warrant use of this intervention.	1	2	3	4	5
6. Most teachers would find this intervention suitable for the behavior problem described.	1	2	3	4	5
7. I would be willing to use this intervention in the classroom setting.	1	2	3	4	5
8. The intervention would not result in negative side-effects.	1	2	3	4	5
9. The intervention would be appropriate for a variety of children.	1	2	3	4	5
10. The intervention is consistent with those I have use in classroom settings.	1	2	3	4	5
11. The intervention was a fair way to handle the child's problem behavior.	1	2	3	4	5
12. The intervention is reasonable for the behavior problem described.	1	2	3	4	5
13. I liked the procedures used in the intervention.	1	2	3	4	5
14. The intervention was a good way to handle this child's behavior problem.	1	2	3	4	5
15. Overall, the intervention would be beneficial for the child.	1	2	3	4	5
16. The intervention would quickly improve the child's behavior.	1	2	3	4	5
17. The intervention would produce a lasting improvement in the child's behavior.	1	2	3	4	5
18. The intervention would improve the child's behavior to the point that it would not noticeably deviate from other classmates' behavior.	1	2	3	4	5
19. Soon after using the intervention, the teacher would notice a positive change in the problem behavior.	1	2	3	4	5
20. The child's behavior will remain at an improved level even after the intervention is discontinued.	1	2	3	4	5

21. Using the intervention should not only improve the child's behavior in the classroom, but also in other settings (e.g., other classrooms, home).	1	2	3	4	5
22. When comparing this child with a well-behaved peer before and after use of the intervention, the child's and the peer's behavior would be more alike after using the intervention.	1	2	3	4	5
23. The intervention should produce enough improvement in the child's behavior so the behavior no longer is a problem in the classroom.	1	2	3	4	5
24. Other behaviors related to the problem behavior also are likely to be improved by the intervention.	1	2	3	4	5

Best Practices in Defining Student Goals and Outcomes

Lynn S. Fuchs
Peabody College of Vanderbilt University

OVERVIEW

Definition of the Topic

The importance of goals in understanding human behavior is critical. Individuals organize their activities around goals that relate to their current levels of performance and their aspirations; the nature of an individual's goals and his or her daily strivings are intimately intertwined. Similarly schools are organized around goals related to age-appropriate societal expectations; the nature of those goals and the curricula of schools, or what teachers teach, are inextricably connected.

Clearly written, justifiable goals and procedures for evaluating goal attainment are potentially key factors for successful educational programs. Over the years, the pressure to specify clear, measurable outcomes for individual students has increased dramatically. The purpose of this chapter is to discuss the history, context, purposes, and applications of goals and to present alternative methods for accomplishing the specification of useful, manageable goal statements.

History and Rationale

Before the turn of the twentieth century, psychologists viewed the brain as a composite of general intellectual faculties that, when strengthened, could be applied to any area of human activity. Therefore, if educators identified faculties and strengthened them, they would expect concurrent educational growth.

At the turn of the century, however, Thorndike demonstrated the specificity of transfer, such that learning occurs when elements in the original context are relevant and similar to elements in other contexts. Applying Thorndike's work to the development of educational curricula, Bobbitt (1918) argued that human life consists of performing specific activities, and that the skills and knowledge required for successful adult life should constitute the curriculum of schools.

Consequently, psychologists began to develop the notion that general intellectual growth might be operationalized to include a series of learning products. This premise was central to Ralph Tyler's work in curriculum and instruction. Tyler argued that evaluation demonstrated the ways and extent to which students have changed in relation to a set of desired behaviors. While in charge of the eight-year study of secondary education for the Progressive Education Association, Tyler emphasized successfully the need to define educational goals in terms of student behaviors and specific content. A product of that study was Smith and Tyler's book, *Appraising and Recording Student Progress* (1942), which lists numerous behavioral objectives. As director of the National Assessment Project, Tyler required that educational objectives constitute the groundwork for developing curriculum materials and instructional procedures and in designing evaluation instruments to appraise the effectiveness of these newly developed materials and procedures (Bloom, Hastings, & Madaus, 1971).

Psychologists such as Gagne, Glaser, and Mager also attempted to develop clear statements of educational objectives. However, unlike Tyler, who was interested in evaluation, these investigators were interested primarily in the development of effective instruction. Their focus was on task analysis: the description of behavioral outcomes in terms of a repertoire of discrete behaviors that must be built sequentially to arrive at a terminal performance. The work of Gagne and others developed further the notion that school-related growth could be operationalized and segmented into very small units.

Perhaps one of the major effects of the use of distinct behavioral objectives in schools was to render local educational agencies more accountable to the public for the content and effectiveness of their programs. Similarly, in special education, accountability was one of the important rationales for mandating the development of Individual Educational Programs (IEPs), which include annual goals and short-term objectives. Developers of PL 94—142 intended that the IEP statement of goals, along with procedures and criteria for determining whether goals are being met, would assure that schools were accountable to students, parents, and taxpayers for the quality of the programs they provided to students with disabilities (Turnbull & Turnbull, 1978). Unfortunately, in the first two decades of PL 94–142's implementation, accountability focused almost exclusively on procedural compliance — documenting that goals and objectives were written and that services were provided.

Current Context

More recently, as concern about this country's academic and workplace competitiveness has increased, the demand for accountability for student outcomes has increased within special education and spread across the entire educational system. In September 1990, then-President George Bush convened a historic education summit with the nation's governors at the University of Virginia — the only time in our country's history that such a summit has been held to discuss issues pertaining to education. In his concluding remarks, President Bush discussed the overwhelming need to establish "accountability for outcome-related results."

This focus on student outcomes is reflected in a recent Gallup Poll, in which 70% of Americans favored requiring schools to conform to national standards and goals. Likewise, Ernest L. Boyer observed, "I think we've gone about as far as we can go in the current reform movement dealing with procedural issues. . . . Schools [should] be held accountable for outcomes rather than the current situation of heavy state regulation that 'nibbles' them to death over procedures."

This distinction between procedural and outcome accountability is particularly relevant to special education. As stated, since 1975, when PL 94–142 was passed, the field has witnessed a 20-year focus on procedural compliance. In 1995, however, in synchrony with the accountability movement in general education, the field has begun to refocus attention on what students are learning, rather than what services are being provided.

As we enter the second half of the last decade of the century — when resources are becoming tighter, when we increasingly are competing economically in an international marketplace, and when the disparities between the wealthy and poor are growing — accountability has become the operant word in justifying increased funds for schooling. The public requires that schools demonstrate student improvement — or results — to justify increased expenditures, including funds for special education.

Purposes

As the pressure to account for the effects of schooling continues to mount, the critical issue is how to define our goals so they represent the most important outcomes for our students to achieve. In considering alternative methods for specifying our goal statements, three purposes are critical: to direct teaching and curriculum development, to guide learners, and to structure evaluation and accountability.

Directing teaching and curriculum development. Studies indicate that teaching with goals fosters student academic growth and teacher success. In an early study, for example, McNeil (1967) randomly assigned 77 university teacher trainees to two groups. In the experimental group, trainees contracted with their cooperating teachers for the student changes that would constitute success; in the control group, practicing teachers familiarized themselves with class activities and prepared daily lesson plans. Both supervisors and cooperating teachers judged the experimental trainees' success in teaching by pupil achievement and the trainees' applications of learning principles. In a related experiment, McNeil (1967) added to these findings by demonstrating that student teachers effected superior student growth when their own grades depended on the appropriateness of the goals they selected for their students and on their students' mastery of those goals. Additional studies through the years have corroborated McNeil's early work, indicating that teaching with specific goals focused on student outcomes increases teacher success and student achievement.

Guiding learners. Industrial and social psychology studies of individual and group goals suggest that an individual functions better when clear about expected goals. Learning theory also supports the importance of students being aware of the goals toward which they strive: Such understanding theoretically helps learners recognize errors and improve performance, and this power to discriminate among responses affects their attainment of skills. In addition, a substantial number of studies has documented that student knowledge of goals enhances learning.

Structuring evaluation. As already discussed, a primary impetus for the use of goals in education has been to structure the evaluation, or accountability, process. Once a well-formulated goal has been specified, it structures the methods for assessment and evaluation.

Applications for School Psychologists

With changing demographics in the school-age population, school reform efforts that focus more on collaboration among professionals, and inclusion of disabled students within general education classrooms, the need for solving individual student problems should increase and school psychologists' roles should continue to become more varied. Consequently, the need for school psychologists to assume the role of problem solvers and to adopt a problem-solving approach to their professional activities should grow.

The concept of a problem-solving approach, as presented in this volume, is characterized by defining problem behaviors in behaviorally specific and discrete form, assessing those behaviors using low inference methods, setting goals in relation to baseline levels, formulating interventions to ameliorate problem behaviors, direct and frequent monitoring to gauge progress, and terminating services when goals have been realized. Central to guiding a successful problem-solving approach, consequently, is the definition of the problem and specification of the goal: With a well-specified goal, evaluation is structured, teaching and intervention are directed, and learners are guided toward problem solution. In school settings where a problem-solving approach is central to innovation, school psychologists must be prepared to assist fellow professionals in developing important, useful goal statements.

BASIC CONSIDERATIONS

Background for School Psychologists

Increasingly, school psychology training programs have broadened their focus from psychometric principles and test administration, interpretation, and reporting to preparing future school psychologists to assume critical roles in coordinating and improving academic and psychosocial treatments delivered within school settings. In preparing for their important role in helping schools delineate desired outcomes for their students, school psychologists must rely on consultation and collaboration skills, a thorough grounding in academic curricula, psychosocial treatments, workplace and community contexts, and complete understanding of alternative strategies for monitoring student progress toward anticipated outcomes.

Principles for Useful Goal Statements

This section reviews basic considerations for writing useful goal statements. Effective goals must be student-centered, clear and precise, ambitious, focused on long-term outcomes, descriptive of generalizable behavior within authentic settings, and developed through collaboration.

Student- versus teacher-centered goals. In useful goal statements, the verb does not describe teacher activities (e.g., the teacher will teach early civilization). Such statements of teachers' plans are helpful only after we have determined what we want students to accomplish. Consequently, outcomes that describe what we want students to accomplish should focus the direction and evaluation of instruction and, correspondingly, our goal statements.

The relationship between teacher- and student-centered goals is analogous to the relationship between learning processes and learning products. For Teacher A, learning might include having students trace letters in the air and complete Frostig worksheets; for Teacher B, learning might include providing phonics instruction and lots of opportunity for students to read literature. In both cases, however, the learning product — or goal — is identical: reading first-grade text proficiently.

As this example illustrates, goals should not outline the instructional methods or the content to be covered in a curriculum. Goals that do focus on instructional methods or content coverage are met when the instruction has been provided or the content has been presented — regardless of whether students have changed in any intended way. Unfortunately, in many school districts today, a strong emphasis on content coverage exists, pressing teachers to cover material in lockstep fashion, regardless of whether students are learning the material. Instead, goals should focus on student mastery.

Clear and precise goals. Research (e.g., Melton, 1978) indicates that the more clear goals are, the more likely participants are to attempt to meet them. Dales (1970) underscored this point by demonstrating that student performance was significantly better when students were given precisely rather than vaguely stated goals. This finding corroborates learning and measurement theory: Clear goals provide more useful information both to learners for discerning correct performance and to professionals for structuring instruction and evaluation.

Ambitious goals. If we accept the premise that goals are important in directing human behavior, then the ambitiousness of goal must be critical in determining how functional the goal will be. If goals are too easy to attain, they fail to sustain meaningful behavior. If, on the other hand, they are exceedingly difficult to achieve, they may discourage functional behavior.

Within educational settings, unambitious goals, which are relatively easy to achieve, may allow educators to appear more successful than they really are. By contrast, appropriately ambitious goals, which may reduce the appearance of success in the short run, may intensify programs and enhance outcomes in the long run.

In investigating goal ambitiousness, Fuchs, Fuchs, and Deno (1985) explored the relation between student achievement and goal ambitiousness and goal mastery. Participants were 58 special education students for whom teachers assessed baseline performance and set reading goals employing a standard format. On the basis of the relation between baseline and the stated goal, students were assigned to highly ambitious, moderately ambitious, and low goal groups. For 18 weeks, teachers worked to achieve their goals. Student achievement was measured at the beginning and end of the study; at the end, goal mastery was determined. Analyses revealed that the ambitiousness of the goals was associated positively with achievement. Goal mastery, however, was not. That is, teachers who geared their efforts toward more ambitious goals achieved better results, regardless of whether or not students actually met their goals.

In a related study, Fuchs, Fuchs, and Hamlett (1989) contrasted two decision-making structures used in conjunction with an ongoing assessment system, Curriculum-Based Measurement (CBM). Ten teachers participated in a contrast group in which CBM was not used. Ten teachers participated in a conventional CBM treatment in which, once the goal was specified at the beginning of the year, teachers were free to increase their goal at any time; the formal decision rules, however, never required them to increase the goal. The final group of 10 teachers participated in a CBM treatment in which the decision rules prompted an increase in the goal whenever the student's performance indicated that the student might be able to surpass the initially specified goal.

At the end of a 15-week treatment period, results indicated that teachers in the goal-raising treatment actually did increase goals more frequently than the conventional CBM treatment teachers. Moreover, as might be expected, the goals of the goal-raising teachers were more ambitious than those of the conventional CBM treatment teachers by the end of the study. Most important, however, the achievement of the students in the goal-raising treatment surpassed that of the contrast group, whereas the achievement of the conventional CBM treatment group did not.

Consequently, it appears important that practitioners specify ambitious goal statements. Unfortunately, guidelines for determining ambitious goals for individual students are difficult to identify. Later sections of this chapter will review some specific methods for monitoring goals and ensuring appropriate goal ambitiousness.

Long- versus short-term goals. A basic distinction between classes of goal statements is whether they focus on what the student will accomplish in a short time frame — within the next week or month — or on what the student will accomplish in a longer time frame — by the end of the year.

With a short-term goal approach, the teacher specifies a hierarchical curriculum, representing the sequence of skills to be mastered during the year. Each skill in this hierarchy then becomes the target of one short-term goal. For example, if the teacher planned for the student to master phoneme-grapheme associations at the beginning of the year, the teacher would specify a goal indicating mastery of phoneme-grapheme associations, and would focus on this goal until mastery was demonstrated. The teacher would then focus on the next goal in the hierarchy: perhaps reading consonant-vowel-consonant words. In this way, throughout the year, the teacher would periodically shift goal statements as skills in the hierarchy were sequentially mastered.

By contrast, with a long-term goal approach, the teacher specifies an annual goal and creates a large pool of related measurement items. For example, if the long-term goal were for the student to read third-grade text proficiently, a large pool of reading passages representing third-grade text would be prepared, from which passages could be drawn for frequent measurement of the student's reading proficiency. Regardless of the teacher's current instructional methods, the goal statement (and its related measurement strategy) would remain constant.

Short- and long-term goal approaches differ conceptually and practically. With a short-term goal approach, the goal focuses on the current instructional material and makes goal attainment relatively easy to realize. Because of these dimensions, short-term goals are relatively sensitive to the effects of instructional programs, and therefore can be satisfying for teachers and students.

However, a short-term goal approach also has distinct disadvantages. First, because the goal structure requires mastery of one goal before instruction on the next goal can begin, the validity of this hierarchy for an individual child is critical. Unfortunately, the hierarchy specified with a short-term goal approach almost always is hypothetically rather than empirically determined and, therefore, often of questionable relevance for an individual child. Second, because a short-term goal approach focuses on one skill at a time, it does not address cumulative mastery and coordinated use of multiple skills. Consequently, it is not unusual, especially for students with learning difficulties, for teachers to find that although students have mastered single skills sequentially through the year, those students have failed to demonstrate the capacity at the end of the year to integrate the multiple skills. Such a failure may explain the documented, relatively poor relation between number of skills mastered during the year and performance on end-of-year global achievement tests. Essentially, although it takes longer to see student improvement with a long-term goal approach, long-term goals better represent the ultimate desired outcome that we want to see students demonstrate.

At a practical level, a long-term goal approach offers additional advantages because, typically, only one goal statement is needed to describe the outcome we expect within a given domain. This translates into one elegant system for monitoring the student's acquisition of desired outcomes. By contrast, a short-term goal approach requires many different goal statements, and, for each statement, a different system for monitoring mastery. This can produce a complicated, unmanageable system. For example, Safer and Hobbs (1979) reported that nearly one-quarter of the IEPs they examined were at least 11 pages long, with goal statements comprising most of the documents. These goals covered small details that essentially outlined the components of the instructional programs the students were to receive. Numerous, specific goals render the task of monitoring progress cumbersome: With an excessive number of goals to track, teachers are faced with the overwhelming task of designing and administering measurement procedures for multiple goals, a situation that often leads to infrequent compliance with the IEP monitoring requirement (Thurlow & Ysseldyke, 1979). A long-term goal approach can streamline the process of monitoring goal attainment and thus enhance compliance.

Description of generalizable behavior within authentic settings. Related to a focus on long-term goals is the notion that, to the greatest extent possible, goals should describe generalizable behavior within authentic settings. To understand this principle, consider the following proposition: Goals that focus on reading connected text represent more generalizable behaviors and are more applicable to real-world tasks than are goals that focus on reading lists of r-controlled words. Similarly, goals that focus on spelling words correctly within naturally written compositions represent more generalizable behaviors and are more applicable to real-world tasks than are goals that focus on spelling lists of dictated words.

The extent to which we can focus our goals on the real-world outcomes we desire of students, the greater the probability that the instruction teachers provide and the evaluation methods they employ will enable students to acquire important, global skills. Consequently, goals should be statements about broad skills within even broader domains. They structure what broad skills a child will attain over a relatively long time. Relevant questions for practitioners to ask as they consider alternative goals are: Is this outcome necessary for students to function ultimately in complex heterogeneous community settings? Could students function as successful, employed adults if they did not accomplish this outcome? Do other, more important outcomes exist relating to overall academic or social competence?

Goals developed through collaboration. Useful goals are formulated through collaboration among multiple perspectives about what constitutes critical outcomes for an individual child. Relevant participants include current teachers across different subjects or settings; future teachers who will receive students at higher grades or in less restrictive settings; parents; community representatives, including potential employers, coaches, and church leaders, as well as current and former students. Because of their training in collaboration and consultation, school psychologists can be the ideal professionals for coordinating such a collaboration.

BEST PRACTICES

This section presents three practices for identifying and monitoring the attainment of critical outcomes: goal attainment scaling, curriculum-based measurement, and a standard core of outcomes. In addition, once the critical outcome has been identified, a level of desired performance typically must be specified. Therefore, this section also reviews three strategies for selecting performance levels: referencing goals to interindividual norms, employing intraindividual norms, and comparing an individual's own performance over time.

Practices for Identifying and Monitoring the Attainment of Critical Outcomes

Goal Attainment Scaling. Goal Attainment Scaling (GAS) (Carr, 1979) establishes goals and specifies a range of outcomes that would indicate progress toward achieving those goals. GAS comprises four essential steps. First, the teacher, student, parents, and principal decide mutually on general goals, such as "improved personal grooming" or "reduced errors in number facts." Second, each participant assigns a weight or number value to each general goal, so that the summed weight across all the general goals equals 100. Third, the teacher breaks down each goal into concrete behaviors. These behaviors represent a continuum of alternative behavioral outcomes, ranging from most to least desirable, within each general goal; a description of the likelihood that the behavioral statement will be achieved is attached. Finally, a student's functioning at any given time is described numerically: Within a goal, the best-fitting behavioral statement (with its corresponding numerical value) is identified; across goals, the products are summed.

In terms of the principles specified above, GAS satisfies some criteria for useful goals more than others. Its strengths include a focus on student outcomes rather than teacher outcomes; its clarity and precision; its potential for encouraging ambitious outcomes; and its deliberate emphasis on collaboration for formulating outcomes. Depending on how GAS is implemented, however, it does not necessarily satisfy the criterion for a long-term approach to goal setting, and it may fail to meet the critical condition that the goal behavior focus on generalizable behavior necessary in authentic settings. Nevertheless, if practitioners focus participants on long-term outcomes that require generalizable behavior in authentic settings, GAS can meet the multiple principles offered in this chapter for useful goals.

Curriculum-Based Measurement. Curriculum-Based Measurement (CBM) (Deno, 1985) is a set of procedures for monitoring student progress. Monitoring student progress requires identifying the goal toward which progress is aimed. Consequently, a major dimension of CBM methods is goal specification.

Within the CBM research program, questions about how to specify goals became subsumed under the larger question of "What to Measure" (see Deno &

Fuchs, 1987). In studying what to measure, CBM developers specified alternative procedures for measuring a student's proficiency within a domain (e.g., in reading: answering questions about the content read, reading list of words aloud, reading connected text aloud, or restoring missing words in text). Then the researchers investigated how well each procedure (a) related to other socially important measures of proficiency, (b) could be implemented accurately, (c) reflected student growth, (d) could be integrated for frequent measurement within the context of busy, complicated classroom settings, and (e) could be used by teachers to improve their instructional program and enhance student achievement.

In each content area (reading, spelling, written expression, and mathematics), one or two alternative formats for specifying annual outcomes satisfied for multiple criteria. For example, research (see Shinn, 1989, for synthesis) indicated that reading connected text aloud was a critical indicator of overall reading proficiency. Reading aloud from connected text (a) related well to many other socially agreed-upon indicators of reading proficiency, (b) was simple and straightforward so that it could be implemented accurately, (c) reflected student growth as it occurred, (d) could be integrated into busy classroom settings, and (e) could be used by teachers to improve their instructional programs and enhance student achievement.

This overall indicator of reading proficiency — reading connected text aloud — could be incorporated in end-of-year goal statements to represent the outcome teachers expect in literacy. Given the principles specified earlier, reading connected text aloud meets the requirements for useful goal statements: It specifies what students, rather than teachers, will accomplish; it communicates clearly and precisely about expectations; it can be used to frame ambitious levels of desired performance; it focuses students and teachers on the long-term outcome; that long-term outcome represents generalizable behavior, which requires integrated performances of multiple skills (e.g., reading words with different phonetic patterns, reading sight vocabulary, using comprehension to enhance fluency, and the like) and which is necessary in authentic settings; and the level of desired behavior or the text within which the performance will be expected can be specified through a collaboration of individuals with a variety of perspectives.

In addition, CBM provides an elegant system for monitoring students' goal attainment. Within an academic domain, it requires practitioners to measure only one, integrated system that simultaneously represents the multiple components of the teacher's curriculum and instructional program. Therefore, it can be used efficiently and feasibly.

Standard core of outcomes. The notion of a standard core of outcomes represents an extension of CBM. The basic idea (Deno, 1993) is that within any behavioral domain, the field can identify standard tasks that (a) represent overall indicators of proficiency, (b) can be used to specify the outcomes of schooling that are critical to successful life-long adjustments, and (c) can structure a measurement process whereby practitioners can efficiently monitor a student's standing and attainment of critical outcomes.

Although a comprehensive system of standard outcomes has yet to be developed, the initial work on CBM in reading, spelling, written expression, and mathematics provides a model for subsequent development of such a system. A key distinction is that, unlike those for CBM, the goal statements within a comprehensive system of standard outcomes is not linked to the student's curriculum. An advantage of disconnecting the specification of goals or outcomes from the student's specific curriculum is that all students may be described in reference to the same standard; this facilitates comparisons across specific settings and contexts.

In all other ways, however, a system of standard outcomes should enjoy the benefits of a system such as CBM: The outcomes are student-centered, are clear and precise, can encourage ambitious expectations, and focus on long-term goals and generalizable behavior in authentic settings. Moreover, such a system requires collaboration among multiple perspectives.

Practices for Selecting Levels of Performance for Goals

Once a basic framework for specifying goals has been identified, the difficult task of selecting a level of desired performance remains. Consequently, if the school psychologist determines, in coordination with school staff, that a GAS framework will be adopted, he or she still must identify what levels of outcomes should be incorporated into, for example, the on-task goal statement (e.g., most unfavorable outcome: student is on task 10% of the time; less than expected outcome: student is on task 25% of the time; expected outcome: student is on task 50% of the time). If the school psychologist determines, in coordination with the school staff, that a CBM framework will be adopted, he or she still must identify what levels of outcomes should be incorporated into, for example, the reading goal statement (e.g., Given third-grade passages from the Holt curriculum, the student will read 125 words correctly in one minute). The next section reviews alternative strategies for identifying levels of performance for goal statements.

Referencing to interindividual norms. As illustrated in the early work of Deno and Mirkin (1977), one sensible strategy for selecting levels of performance for goals is to measure other, more proficient students' levels of performance in the relevant domain and to set the target student's goal so that he or she will demonstrate performance commensurate with that of the more competent peers.

In the most simple, manageable version of interindividual norm referencing, a school psychologist may sample several students within a general education classroom at the appropriate grade level. Let's say, for example, that Charlie, a student with a learning disability, is receiving reading instruction within the special education resource room. The special educator deems fourth-grade material a reasonable level of difficulty within which the student may achieve competence by the end of the year. The teacher specifies the goal as: Given fourth-grade passages from the Holt series, Charlie will read X words correctly within one minute. The teacher does not, however, have a concrete way of operationalizing "competence" for specification in the goal statement; that is, the teacher does not know how many words Charlie should read correctly to denote proficiency. The school psychologist can assist the teacher by sampling three to five students from two different fourth-grade classrooms; having each student read fourth-grade passages for one minute, averaging the scores, and using this number to denote proficiency for Charlie.

This method has the advantage of being empirically based, even as it focuses the teacher on a level of proficiency that should allow the target student to re-enter a less restrictive setting — should the goal be achieved. Nevertheless, this method is also problematic because while Charlie is striving toward the empirically derived criterion of performance, his general education peers also are improving. Therefore, when Charlie achieves the specified goal, his general education peers will have surpassed Charlie's achievement.

At least partly because of this problem, some school systems have established norms for their school district or schools, within their selected goal framework. Some districts that rely on CBM methods for goal specification, for example, have collected norms describing how many words per minute typical students in their schools read aloud from grade-level material at the beginning, middle, and end of the academic year. With such norms routinely available, practitioners have a data base that allows appropriate interindividual goal levels to be specified at any time. Shinn, Tindal, and Stein (1988) describe methods for collecting local CBM norms.

Referencing to intraindividual norms. Interindividual norms for setting goals are empirically defensible; they allow special educators to set their expectations in terms of how students within general education perform, and facilitate sound decisions about when students with disabilities may be moved across instructional settings. Unfortunately, this method of establishing performance criteria does not consider a student's beginning-of-the-year performance: All third graders may have year-end reading goals set at the normatively appropriate level of 125 words read correctly per minute (WCPM). However, for a student with a beginning rate of 75 WCPM, this goal would represent an expected weekly increase of 1.67 WCPM ([125–65] + 30 weeks); for a student with an incoming rate of 25 WCPM, the expected weekly increase would be considerably larger ([125 –25] + 30 weeks = 3.33 WCPM). Consequently, relying on cross-sectional normative data can produce varying standards for weekly rates of growth.

One alternative method is to monitor intraindividual student progress over time and to calculate normative data directly from students' weekly rates of improvement. With such a method, students in a school district are monitored by the number of words they read aloud from text each week. At the end of the year, the average weekly rate of improvement is derived for typical students at each grade level within a performance domain. The weekly rate of improvement is then used to specify the performance criterion.

For example, as illustrated by Fuchs, Fuchs, Hamlett, Walz, and Germann (1993), second-grade students, when measured each week by the number of words read aloud from text in one minute, typically increase 1.46 words each week. Consequently, if a goal were specified for a student to read second-grade text, a teacher could select a performance criterion that establishes a weekly rate of growth commensurate with what we would expect normally achieving second graders to demonstrate — approximately 1.50 words per week. So, if the student initially read 35 WCPM from second-grade text, the performance criterion might be 80 WCPM ([1.5 x 30 weeks] + 35). Although this outcome may not place the student at a level commensurate with normally achieving second graders at year's end, it would denote a rate of progress commensurate with normally achieving second graders.

Interindividual comparisons over time. A third option for specifying the performance criterion also involves empirical determination. In contrast to an interindividual or an intraindividual normative approach, however, this third option does not rely on other children to derive the empirical determination. Rather, it relies on the student's own rate of improvement to formulate the end-of-year goal in a data-based, dynamic (i.e., ever-changing) way.

As illustrated by Fuchs et al. (1989), after a teacher relies on professional judgment to specify an initial performance criterion, he or she continuously monitors the student's progress. When the student's rate of progress matches or exceeds the rate of improvement specified in the initial goal, the teacher increases the end-of-year goal, in an attempt to maintain ambitious goals, relative to what the student is demonstrating he/she can achieve.

For example, let's say that the student's baseline performance is 35 WCPM in fourth-grade text and that the teacher's best judgment is that for the end-of-year goal (30 weeks away) the student would read 70 WCPM in fourth-grade text (a weekly rate of improvement of 1.16 words [70–35]/30 weeks). After six weeks of implementing the instructional program, the teacher finds that the student is increasing his/her weekly score by 1.6 words. At that time, the end-of-year goal would be reset to 83 (after six weeks, the student's current performance level is 44.6, i.e., [1.6 x 6 weeks] + 35 baseline; for the next 24 weeks, the teacher will not expect a continued weekly increase of 1.6: [1.6 x 24 weeks] + 44.6 = 83). The teacher continues to monitor the student's performance each week. Whenever the student's weekly rate of improvement increases, the goal is reset accordingly — always using the student's own best performance to determine an appropriately ambitious performance criterion for that student.

SUMMARY

This chapter focused on specifying student goals and outcomes, in order to direct teaching and curriculum development, guide learners, and structure evaluation. Goals should be student-centered, clear and precise, ambitious, focused on long-term outcomes, descriptive of generalizable behavior useful within authentic settings, and developed through a collaborative process. Given these considerations, three alternative frameworks for specifying goals — Goal Attainment Scaling, Curriculum-Based Measurement, and a Standard Core of Outcomes — are useful to varying degrees. Finally, three empirical strategies can be used to specify performance criteria: interindividual norms, intraindividual norms, and referencing to an individual's own ongoing performance.

Best Practices in Curriculum-Based Measurement and Its Use in a Problem-Solving Model

Mark R. Shinn
University of Oregon

Curriculum-Based Measurement (CBM) is the use of standardized and validated short-duration fluency measures of basic skills by special education and general education teachers for the primary purpose of evaluating the effects of their instructional programs (Deno, 1985, 1986; Fuchs & Deno, 1991). Given this principal use, a logical question arises: Why should school psychologists be interested in CBM? The reasons are multi-fold and can be divided into two broad categories: (a) concerns about the programs and services for students with disabilities, and (b) concerns about the educational and psychological needs of all children. This chapter provides a rationale for use of CBM by school psychologists and other educators in a *problem-solving model* and details how CBM is used in decision making via a case study.

Special Education Concerns

Three major concerns related to school psychology practice can serve as compelling reasons why school psychologists should be interested in CBM: (a) effective special education programs, (b) the lack of quality for the Individualized Education Plan (IEP) goals and objectives, and (c) the misalignment of assessment and intervention. A survey of members of the National Association of School Psychologists (NASP) by Reschly, Genshaft, and Binder (1987) provides considerable information about some of these concerns. Reschly et al. (1987) surveyed 600 NASP practitioners, 139 leadership staff, and 166 faculty members on a variety of contemporary practice issues, including assessment practices and special education service delivery.

Lack of special education effectiveness. Among the Reschly et al. (1987) survey's findings is the striking discrepancy between the major activity of school psychologists, testing for special education eligibility (Hutton, Dubes, & Muir, 1992; Smith, 1984), and the perceived consequences of this activity for many students with disabilities, ineffective special education programs. Only about one-third (32%) of responding practitioners agreed with the statement that special education services are usually quite effective. Even fewer school psychology faculty (about one in 19) agreed with the effectiveness statement. These professional opinions are echoed by meta-analyses of special education effectiveness that provide little evidence of powerful special education programs (Carlberg & Kavale, 1980; Forness & Kavale, 1987; Kavale & Forness, 1985, 1987).

CBM can be used to improve special education students' achievement outcomes significantly. Repeated studies by L. Fuchs and D. Fuchs (e.g., Fuchs, Deno, & Mirkin, 1984; Fuchs, Fuchs, & Hamlett, 1989; Fuchs, Fuchs, Hamlett, & Allinder, 1991; Fuchs, Fuchs, Hamlett, & Ferguson, 1992; Fuchs, Fuchs, Hamlett, & Stecker, 1991) have shown that when teachers use CBM to write data-based goals, monitor the effects of their instructional programs, and adjust their interventions when the data show little outcome, student achievement improves. Typical effect sizes, the amount of standard deviation gains in achievement attained by members of the treatment group versus controls, exceed one half standard deviation. Because school psychologists are concerned about the limited or negligible effects of special education, they should be interested in implementing CBM to enhance student outcomes.

IEP goals and objectives. Another concern tied to the lack of special education outcomes is the quality of special education students' IEP goals and objectives. Without quality goals and objectives, evaluation of individual student's outcomes is problematic, and as a result, ineffective interventions will not be identified and modified. Special education legislation (e.g., the Individual Disabilities Education Act) recognizes the needs for evaluation of individual program outcomes and therefore mandates that each student with a disability have a statement as to what the intervention is designed to accomplish on at least an annual basis. However, 16 years after implementation of the landmark law ushering in the IEP mandates, the Education for All Handicapped Children Act, the quality of IEPs has not improved significantly (Smith, 1990). Typically, IEP goals are written without current student performance data; are vague and lack observable, measurable outcomes (e.g., "Will improve 1 year in reading"); or detail lists of isolated short-term instructional objectives (e.g., will master C-V-C words with 80% accuracy). Compounding the problem of difficult-to-measure goals is the lack of consensus as to what student goals should be. Too often, special education goals are procedurally driven (e.g., dictated by "district policy") as opposed to a meaningful discussion as to what an individual intervention program is designed to accomplish. This proceduralism may explain the apparent lack of substance in IEP goals and objectives, the observation that two-thirds of IEPs are written before or after the IEP meeting (Smith, 1990), and the reported problems in getting general education teachers and parents involved in the process (Huebner & Gould, 1991).

CBM is a technology that has been validated for use in writing data-based, observable and measurable IEP goals and objectives (Fuchs & Shinn, 1989). In fact, CBM's research-based development was supported by federal funds to identify a technology to assist in implementation of the original Education for All Handicapped Children Act, PL 94-142 (Deno, 1992).

Linking assessment and intervention. The third major special education concern for school psychologists is the lack of treatment validity of their assessment data. Information collected most often comes from published norm-referenced tests of aptitude and achievement (PNTs). Extensive discussion as to the limited treatment utility of PNTs is beyond the scope of this chapter. The reader is encouraged to see Marston (1989) or Howell, Fox, and Morehead (1993) for a more extensive discussion of this topic. In brief, although many PNTs are generally well constructed as *broad* measures of constructs or skills, the very nature of their broad-band precludes their usefulness for intervention planning. The tests have too few items, many of which are not tied to any particular curriculum and the limited number of items are spread across too large an age span. These problems lead to questionable conclusions about what a student can or cannot do correctly and what a student needs to learn to be successful in a *specific* classroom curriculum. Additionally, PNTs rely almost exclusively on selection-type response formats (e.g., pointing to one of four choices) that are not "authentic." These types of responses provide information only on correctness, not on what strategies or preskills a student brings to bear on a task (Howell et al., 1993).

CBM can be of use to school psychologists in special education intervention planning because it links what is measured to what is taught. CBM measures are very narrow band in test content; test items typically encompass only 1 year of a curriculum for each level of the test. *All* items are derived from the curriculum used in general education classrooms, and thus maximize testing/teaching overlap. Finally, CBM relies heavily on production-type, authentic response modes. Students read aloud from text, write dictated spelling words, write answers to mathematics computational problems, and write stories. These types of responses allow for information to be gained not only about correctness, but *how* and *why* students answered in specific ways.

Educational and Psychological Concerns of All Children

Significant numbers of children, not all of whom receive special education, experience achievement and social-emotional problems in schools. The end result is high rates of school dropout and illiteracy. National dropout rates currently are around 30% for high school students (Center for the Study of Social Policy, 1991) and are even higher for students from minority backgrounds. The consequences of school dropout are serious, including limited earning power. For example, students without a high school education have twice the unemployment rate and have experienced a 42% decrease in earning power between 1973 and 1986 alone in constant 1986 dollars (Carnegie Council on Adolescent Development, 1989). Significant numbers of students also are exiting schools as functionally illiterate. Adams (1990) reports that nearly 85% of adjudicated youth are functionally illiterate. Estimates of illiteracy rates among minority youth are approximately 40%. High school dropouts and functionally illiterate adults are losing competitiveness in an ever more technological economy.

Unfortunately, special education has served as *the* primary mechanism for resolving the widespread achievement and social-emotional problems of children in schools. School psychologists are well aware of this situation. Reschly et al. (1987) reported that nearly two-thirds of school psychology practitioners and nearly 90% of the NASP leadership agreed that students are classified as learning disabled (LD) so that services can be provided even though they are not really handicapped. A similar proportion of practitioners (64%) and of the NASP leadership and school psychology faculty (80%) agreed with the statement that too many students are classified as LD and placed in special education. More than 70% of practitioners and faculty and 90% of NASP leaders agreed that better regular classroom instruction would prevent many students from being classified as LD.

Education must find more ways of contributing to *all* children's needs than assigning large numbers of students to special education. Increased school psychology assistance to general education teachers and parents can be one such resource (Curtis & Batsche, 1991). The primary obstacle to increased school psychology services to all children is school psychologists' heavy commitment to testing for special education eligibility. CBM can help school psychologists contribute to meeting the needs of more children by reducing these testing demands. When CBM is implemented in a problem-solving model, school psychology testing for special education eligibility is reduced significantly and corresponding increases in intervention services to all children are noted. Such changes were reported by Canter (1991) in Minneapolis Public Schools. Rather than routinely testing every referral for purposes of determining special education eligibility, when CBM was used in a problem-solving model, school psychologists tested students only when there were specific assessment questions. On average, this situation occurred in only half of the school psychologist referrals. Intelligence testing was reduced even further and involved only one-half of the cases where any specific testing was needed.

With this decrease in eligibility testing, changes were observed in school psychologists' intervention activities. Consultation to general education and special education teachers increased from 12% to 36% of cases within 3 years; within 5 years, this figure increased further to 52% of cases (Canter, 1991). This percentage is more than two-and-one-half to almost five times higher than the amount of consultation reported by school psychology practitioners (Costenbader, Swartz, & Petrix, 1992). Fewer than 5% of the national sample surveyed by Costenbader et al. (1992) exceeded the average consultation rates described in Canter's chapter. Canter (1991) also reported increases of direct services to students such as counseling or crisis intervention, an increase from 1.5% to 10% of caseloads.

What Makes CBM CBM?

Given these compelling reasons for school psychologists to be interested in CBM then, the question becomes "just what is CBM?" This question is important to answer because practitioners have encountered a virtual explosion of information in the professional literature on *curriculum-based assessment* (CBA). Among the numerous assessment techniques considered CBA are informal reading inventories, end-of-unit mastery tests, analysis of homework samples, Precision Teaching, and a variety of locally made tests that measure what students are learning. To reduce confusion, it is important for practitioners to discriminate the similarities and differences among the variety of approaches collectively entitled CBA. For more information on this topic, the reader is referred to Shinn, Rosenfield, and Knutson (1989) or Tindal (1993).

In brief, CBA is a very broad term that describes *any* testing strategy that uses a student's curriculum as the basis for decision making. CBM is one type of CBA. Testing is accomplished using a limited number of standardized and validated measures of student performance in the basic skill areas of reading, spelling, mathematics computation, and written expression. Specifically, CBM measures consist of the following core testing strategies:

1. In reading, students read aloud from basal readers for 1 minute. The number of words read correctly constitutes the basic decision-making metric. Maze, a multiple choice cloze reading technique, also has been validated as a CBM testing strategy (Fuchs & Fuchs, 1992). The number of correct word choices per 5 minutes is the primary metric.

2. In spelling, students write words that are dictated at specified intervals (either 5, 7, or 10 seconds) for 2 minutes. The number of correct letter sequences and words spelled correctly are counted.

3. In written expression, students write a story for 3 minutes after being given a story starter (e.g., "Pretend you are playing on the playground and a spaceship lands. A little green person comes out and calls your name and . . ."). The number of words written, spelled correctly, and/or correct word sequences are counted.

4. In mathematics, students write answers to computational problems via 2-minute probes. The number of correctly written digits is counted.

Upon first inspection, CBM may look like a number of other CBA approaches. For example, when reading is tested, students read text aloud in CBM, a process that looks much like an informal reading inventory. Similarly, students typically read aloud for 1 minute, a process that resembles precision teaching. However, these superficial "similarities" should not preclude a careful analysis of how CBM is different from other CBA approaches. CBM differs from other CBA approaches on a number of important features. Among its most obvious features is the short-duration (e.g., 1 to 3 minutes) of each of a limited number of test strategies. Usually, these short duration tests are not drawn from the exact point in a curriculum a student has been taught (e.g., a unit) but from the annual curriculum. A second obvious feature is CBM's reliance on fluency, a combination of accuracy and speed, as the behavior of interest.

CBM as DIBS. Why would a testing strategy place so much emphasis on short-duration fluency measures with such a limited number of different tasks? The best way to understand this approach to assessing student academic performance is to characterize CBM as a set of *DIBS*, or "dynamic indicators of basic skills." The measurement procedures are *dynamic* in that they are designed to be sensitive to the short-term effects (i.e., 4–6 weeks) of instructional interventions; they are designed to assess change. By using short-duration measures, these tests can be administered frequently, allowing change to be assessed on a routine basis. By using fluency, a metric is engaged that is more sensitive to change than other metrics such as accuracy.

The measurement procedures are *indicators* in that they were validated to be correlates of key behaviors indicative of overall performance in an academic area. The CBM measures were *not* designed to represent all behaviors that may be included in an academic domain such as reading. They will not provide direct information about whether a student can separate fact from fiction or identify the compellingness of an author's argument. Nor does their use preclude using other specific skill measures of interest. Should a teacher be interested in a student's fact versus fiction skills, a measure that assesses this specific skill would be appropriate.

Instead, CBM was designed to function like an educational thermometer. A thermometer can do two things especially well: (a) inform a person whether there is a health problem that warrants further investigation (e.g., a temperature of 104.5 F) and (b) tell a treatment provider whether a given intervention is effective (a reduced temperature to 100.3 after aspirin). It is important to note that indicators such as thermometers typically do not tell you directly what is wrong. For example, a thermometer would not inform a physician whether the cause of a high fever was a bacterial or viral infection or the result of appendicitis.

The use of academic "thermometers" requires that reliable and valid indicators be identified. Beginning in 1978, an extensive program of research was undertaken to identify key behaviors that would meet the technical requirements to serve as indicators of academic performance. The short-duration, fluency measures described previously are the results of this research program. Although a considerable body of information has been published on the technical adequacy of CBM in all four academic areas (see Marston, 1989, for an extensive summary), most research has been conducted on CBM reading measures. Results suggest strongly that for most students, oral reading works extremely well as an indicator of general reading proficiency, including comprehension. Evidence has been garnered with respect to construct validity (Shinn, Good, Knutson, Tilly, & Collins, 1992) as well as traditional conceptions of criterion-related validity, including correlations with other accepted published measures (e.g., Deno, Mirkin, & Chiang, 1982; Fuchs, Fuchs, & Maxwell, 1988) and teacher ratings (Fuchs, Fuchs, & Deno, 1982).

Finally, CBM are DIBS in that they are designed to quantify student performance in the *basic skill* areas of reading, spelling, mathematics computation, and written expression. They were not designed to draw inferences about a student's skill in content area courses such as science or health education. Although this basic-skills focus may appear limited in scope, it is important to note the importance of basic skills in the development of functional literacy (Adams, 1990) and the fact that nearly all students in special education are referred because of severe deficits in this area.

In sum, CBM's short duration, fluency measures were designed to fill a void in educational measurement. They were designed as dynamic indicators of basic skills (DIBS) to give educators a simple, straightforward way of determining the status of students' educational health in critical academic areas, and to provide a mechanism for evaluating the effects of efforts to improve any given student's academic health.

CBM and a tie to a Problem-Solving model. CBM can be set apart from other CBA models in that it is tied to an explicit decision-making model. It was stated in the first sentence of this chapter that CBM typically is used by teachers to evaluate the effects of their instructional programs. However, CBM is generally used to do more than accomplish this important endeavor. CBM implementation usually occurs in conjunction with implementation of a Problem-Solving model (Deno, 1989), a heuristic composed of the five major decisions presented in Table 1. Each of the problem-solving model decisions is associated with more familiar terms in special education decision-making jargon (e.g., Salvia & Ysseldyke, 1987). *Problem-Identification* and *Problem-Certification* decisions, for example, are related to the traditional processes of screening and eligibility determination, respectively. *Exploring Solutions* could be considered synonymous with instructional planning. With special education students, this process corresponds to the development of an individual education plan (IEP), including setting annual goals and determining intervention-plan content and process. *Evaluating Solutions* relates to pupil progress monitoring while *Problem Solution* is analogous to program termination or changes in placement to less restrictive settings.

Rather than broad-based undifferentiated data gathering activities and subsequent decision making, the Problem-Solving model dictates that specific information is collected for each step. The need for additional assessment information is decided on a sequential basis. Sometimes, when a problem not be validated, assessment activities stop after the first decision (i.e., Problem Identification). Other times, assessment and decision making may occur on a repeated basis throughout the years spanning a student's educational career. How CBM is used in the problem-solving model will be detailed later in the chapter.

As described by Deno (1989), the Problem-Solving model is predicated on three assumptions. First, a problem is defined as a discrepancy between *what is*

TABLE 1
CBM Problem-Solving Model Decisions, Measurement Activities, and Evaluation Activities

Problem-Solving Decision	Measurement Activities	Evaluation Activities	Specific Tasks
Problem Identification	Observe and record student differences, if any, between actual and expected performance	Decide that a performance discrepancy exists	Peer-referenced assessment
Problem Certification	Describe the magnitude of differences between actual and expected performance in the context of likelihood of general education alone solving the problem	Decide if discrepancies are important enough that special services may be required for problem resolution	Survey-Level Assessments and identification of alternative intervention options
Exploring Solutions	Determine options for annual goals	Decide on anual goal(s) and actual content of intervention to be implemented	Write annual goal based on Survey-Level Assessment; identify specific skill or strategy deficits
Evaluating Solutions	Monitor intervention mplementation and changes in student performance	Determine if intervention is effective or should be modified	Collect progress monitoring data and compare with aimline
Problem Solution	Observe and record student differences, if any, between actual and expected performance	Decide if current discrepancies, if any, are not enough and if special services may be reduced or eliminated	Repeat peer-referenced assessment and Survey-Level Assessment

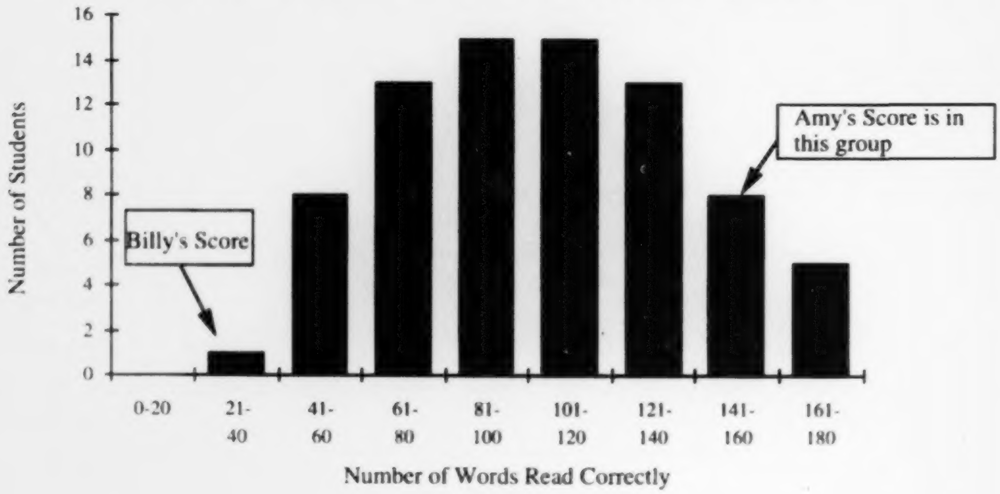
expected and *what occurs*. In an academic context, a problem exists when a student does not perform the academic behavior(s) expected of him or her in a particular curriculum. The implication of this definition is that problems are situational and may not be the student's "internal problem." What is a problem in one context may not be in another. Consider the case of two third-grade students, Amy and Billy. Their classroom teacher would *expect* them to perform in the third-grade curriculum like other students in the classroom. The degree to which they vary from this achievement expectation may result in them being viewed as a problem.

With CBM, it is possible to use a data-based decision-making process to describe Amy and Billy's skills and determining whether there is a problem in a specific environment. Because the CBM measures are dynamic indicators and are of short duration, it is possible to describe the general achievement expectations in particular settings in a time-efficient manner by developing local norms. For more information on this process, see Habedank (this volume) or Shinn (1988; 1989). In Figure 1, Amy and Billy's reading skills relative to the achievement expectations in two school systems are compared. The foundation for the frequency distributions displayed in the Figure are the results of having all third graders, including Amy and Billy, read three randomly selected passages from the typical level of the third-grade general education reading curriculum. Each student's median score is used for summary purposes. Imagine that Amy and Billy's median scores on the third-grade reading passages were 141 words read correctly for Amy and 39 words read correctly for Billy.

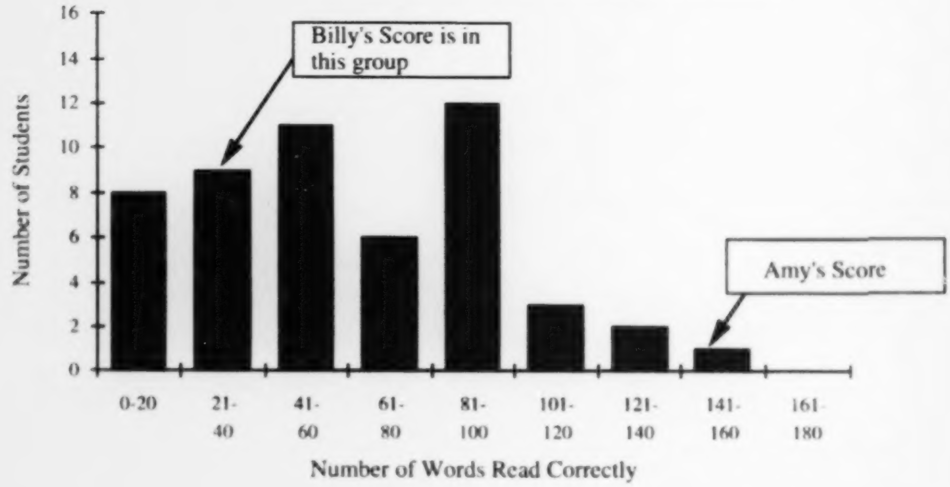
As displayed in Figure 1, reading skills in the third-grade curriculum in School A are distributed normally. Relative to these third graders, Amy is among the top quarter of the group in reading skills. Billy, however, is clearly the lowest performing reader in the curriculum. In this environment, although Amy's instructional needs may be similar to a number of other students, Billy may be considered by the classroom teacher as having a serious reading problem that may require additional accommodations.

In School B, reading skills in the curriculum are not distributed in the same way as School A. The distribution is positively skewed and a substantial proportion of students in the group are reading very poorly in their third-grade instructional curriculum. Therefore, problems may be defined differently. Amy, for example, is now the best third-grade reader and her skills may be so different from others that special accommodations may be necessary to meet her instructional needs. Billy is now no longer easily identifiable as having reading skill deficiencies. Out of 52 third-grade pupils, Billy reads as well or better than one-third (17) of the group. It would be most unlikely

FIGURE 1. A comparison of two students' scores relative to two different environments.



Amy's and Billy's Reading CBM Relative to Third Graders in School A



Amy's and Billy's Reading CBM Relative to Third Graders in School B

that Billy's general education teacher would consider him to have a reading problem that requires special remediation in this context.

In addition to problems being defined situationally as the discrepancy between what is expected and what occurs, the Problem-Solving model assumes that within specific environments, there is a subset of students whose discrepancies are so significant that it may be unreasonable for the to achieve in general education unless their programs are modified (for more detail, see Deno, 1989; this volume). Currently, it remains a value judgment as to when the discrepancy is so severe that special services are warranted, despite repeated attempts to make it quantifiable using a battery of tests and regression formulas. Using CBM in a Problem-Solving model with local norms helps decision makers not only operationalize discrepancies, but also determine whether additional resources such as special education may be required to help students benefit from their education. For example, in School A, Billy has a reading discrepancy that may require additional resources; in School B, a discrepancy is not apparent, although it could be argued that significant numbers of third graders in this school need a change in their reading program because so many third-graders are reading so poorly.

The final assumption of the Problem-Solving model is that effective educators must "generate many possible plans of action prior to attempting problem solution" (Deno, 1989, p. 11) and evaluate the effects of the program actually implemented. Presently, the assessment technology is lacking to say with certainty which instructional program will work with any student. It is not clear whether Billy will benefit from special education (or peer tutoring or Chapter 1) in School A *before* it is tried. Therefore, all interventions should be treated as testable hypotheses that must be evaluated formatively for each individual student. Interventions that show strong positive effects when evaluated are maintained; ineffective interventions are discarded and/or modified.

USING CBM IN A PROBLEM-SOLVING MODEL

The core CBM test strategies are varied systematically and combined with other pieces of information to make one of five decisions in the Problem-Solving model. Depending on the decision to be made, for example, a student may be tested in different *levels* of a curriculum. For example, when making Problem Identification decisions, a student for whom there is a concern (e.g., a third grader) is tested in the level of the general education curriculum (i.e., third grade) in which the typical same-grade peer would be expected to perform satisfactorily. In contrast, when making Evaluating Solutions decisions, a student is tested on curricular materials corresponding to the level of the curriculum in which he or she would be expected to perform in 1 year (i.e., the instructional material that represents the annual goal of the IEP).

In addition to systematic differences in the level of the curriculum tested as a function of the decision to be made, the *decision-making standards* vary as well. Two major approaches are employed, *norm- or peer-referenced decisions and individually referenced decisions.* Some decisions in the Problem-Solving model (e.g., Problem Identification) use a norm- or peer-referenced approach. Decisions are made by comparing an individual student's test results to that of a local norm group. This local norm could represent students from the same class, same school, or same school district. For other decisions (e.g., Evaluating Solutions), an *individually referenced approach* is used. The standard is not how a student's performance compares to a group but how that student's performance compares to his or her previous performances.

Problem Identification

The first step of the Problem-Solving model is Problem Identification. The goal of Problem Identification is to determine in a systematic way if an academic problem exists that is important enough to warrant further assessment (Shinn & Hubbard, 1992). As presented in Table 1, the Problem-Identification process requires a data-based decision about whether a student's performance on academically important tasks (i.e., curriculum tasks) is *significantly discrepant* from that of same-grade peers. For example, in the case of Billy illustrated in Figure 1, at what point is his reading performance relative to other students considered to be so discrepant that it would be validated as a problem? In School A, his performance is the lowest of third graders, but is it *significantly* different? In School B, his performance was more like those of other students. How much like the other students did he perform? Problem Identification attempts to provide some quantification of the differences in curriculum performance to facilitate decision making.

Problem Identification begins like other school practices when someone, usually a general education teacher or a parent, considers a student's skills to be a concern. This concern usually translates into a referral. However, in contrast to prevailing practices where referral leads to special education eligibility testing, in a Problem-Solving model, referrals usually are made to a general education Child Study Team (CST) or Teacher Assistance Team (TAT). After collecting relevant information on student academic performance and school and medical history, the CST decides if a problem is validated and is one that may require significant changes in the student's general education program (e.g., special education; Chapter I) to be resolved. Only should a problem be identified, would more intensive assessment activities such as determining special education eligibility be conducted.

The Problem Identification process has a number of advantages. The first is one of philosophical approach. From the beginning of the process, not *every* potential problem is viewed as a potential special education problem. Referrals that are not validated as potentially significant problems may not necessitate a special education evaluation or special education intervention. Some referral concerns may be remedied based on interventions identified by the CST to occur in general education classrooms. The kind of data collected for Problem Identification is also useful for intervention planning in general education classrooms. The second advantage is that Problem Identification allows for a systematic verification of teacher or parent referral accuracy. Although teachers have been demonstrated to be highly accurate in identifying potential student achievement difficulties (Gerber & Semmel, 1984), they also have been shown to be susceptible to gender and ethnicity biases (Shinn, Tindal, & Spira, 1987). When there is a significant discrepancy, teacher perceptions of a problem are validated objectively. Parent referrals usually result in expensive assessment practices and lower rates of special education eligibility determination than teachers. By systematically collecting Problem-Identification information, the appropriateness of parental concerns can be examined objectively, without expensive special education testing. The third advantage is that the systematic Problem-Identification process can reduce overtesting, an expenditure of limited resources such as school psychologists' and other specialists' time. Those referred students for whom a problem is not identified are not tested. Terminating testing at this point frees up the persons who normally would collect eligibility information to help general education teachers address the student needs in the classroom.

In operation, Problem Identification relies on a norm- or peer-referenced approach. The referred student's level of performance is determined by repeated testing over a short period of time in grade-level curriculum materials in the academic area in which the student is considered to be experiencing difficulty. The student's scores then are compared to an expected achievement level derived from typical students using local norms. Depending on the degree of school system commitment to a Problem-Solving model, the local norms can be derived from students in the same classroom, building, or district. See Habedank (this volume) for more information on this topic. The discrepancy between the student's actual and expected performance (i.e., the achievement level of typical peers) is calculated and a decision regarding the need for further assessment is made via a cutting score.

A critical feature of Problem Identification is that repeated samples of the referred student's current performance are collected daily over a period of 3 to 5 days. Repeated samples provide information about the variability of the student's performance, reduce the effects of "good" days and "bad" days, reduce examiner familiarity effects, and allow for a broader sample of academic behavior.

For illustration of the Problem Identification procedures, consider the case of Sara, who was referred to a CST by her general education teacher during the Fall quarter of third grade because of concerns about her progress in reading and spelling. Because the CST found no obvious reasons for the teacher's concerns (e.g., poor school attendance, vision or hearing difficulties), Sara was tested by a trained member of the CST using a series of third-grade-level CBM probes derived from the general education reading and spelling curricula. The levels of the reading and spelling curricula were the levels in which the typical third grader was expected to perform. In reading, there were two levels of third-grade readers; typical students were expected to be reading in Level 3–2. The CST member had Sara read three different randomly selected passages from Level 3–2 for 1-minute each every day for 5 days. The number of words read correctly and errors were recorded although, for simplification, errors are eliminated in this case study. Sara's reading scores were summarized daily using the median of the three passages.

In spelling, there was only one level of the spelling series. Sara completed a different 2-minute CBM spelling probe with words drawn randomly from all the words in the spelling book on each of the 5 days. The number of words spelled correctly and correct letter sequences, a precise measure of spelling skills, were recorded. For illustration, only correct letter sequence scores will be used here. Sara's 15 reading passage scores, daily reading medians, daily spelling scores, and summary median scores are displayed in Table 2. Table 2 also includes the median reading and spelling scores of 20 randomly selected third-grade students who had been tested using the same materials as part of a school norming process.

To facilitate decision making and increase communication, Sara's scores are displayed graphically in Figure 2. This figure shows Sara's daily median scores in reading and spelling as well as the median performance of other third-grade students in her school. The peer median is represented by the heavy solid line. To decide if a significant discrepancy exists, Sara's scores must consistently fall below a critical value or cutting score, which is represented in Figure 2 by the double line. In this example, the cutting score was based on a *discrepancy ratio* that is calculated by dividing the peer median score by the referred median student's score. Sara's reading discrepancy score was 3.7. The third-grade peer median of 100 words read correctly was divided by Sara's median score of 27 words read correctly. Her discrepancy ratio was 2.3 (123 Correct Letter Sequences/53 Correct Letter Sequences) in spelling. The most common discrepancy ratio used as a cutting score is equal to or greater than 2.0. This score indicates that a student performs at half the fluency (or less) of the typical student in a skill domain. A discrepancy ratio of this magnitude is sufficient to decide that a problem may exist that warrants further assessment.

Discrepancy ratios are used most commonly when local norms are developed for classrooms or schools. When district norms are used, a team has the advantage of more conventional decision-making scores, percentile ranks. Cutting scores based on percentile ranks are determined by finding the raw score that corresponds to an agreed-upon critical level such as the 10th percentile. When a referred student's

TABLE 2
Results of CBM Problem-Identification Testing for Sara

Academic Area Tested	Day					Overall Median	Peer Median
	1	2	3	4	5		
Grade 3–2 Reading Passages							
WRC Passage 1	33	16	32	26	29		
WRC Passage 2	40	27	42	38	24		
WRC Passage 3	38	33	30	25	27		
WRC Daily Median	38	27	32	26	27	27WRC	100WRC
Grade 3 Spelling Words							
CLS	55	45	56	53	49	53 CLS	123 CLS

Note. WRC = words read correctly. CLS = correct letter sequences.

scores consistently fall below the value of scores at the 10th percentile, a problem is identified. If no obvious explanations exist to account for the discrepancy, the student may be assessed further in more detail. In the case of Sara, her median scores would be converted to percentile ranks and compared to the rankings of her third-grade peers from her school district. In reading, her scores fell below the 2nd percentile; in spelling, her scores were at the 5th percentile compared to school-district third graders.

Sara's Problem Identification data consistently were below the discrepancy ratio cutting scores in reading and spelling. Because the team ruled out educational or medical history as viable explanations for Sara's performance, they decided that further investigation of Sara's reading and spelling skills was warranted. For purposes of illustration, only the results of further assessment in reading will be reported.

Problem Certification

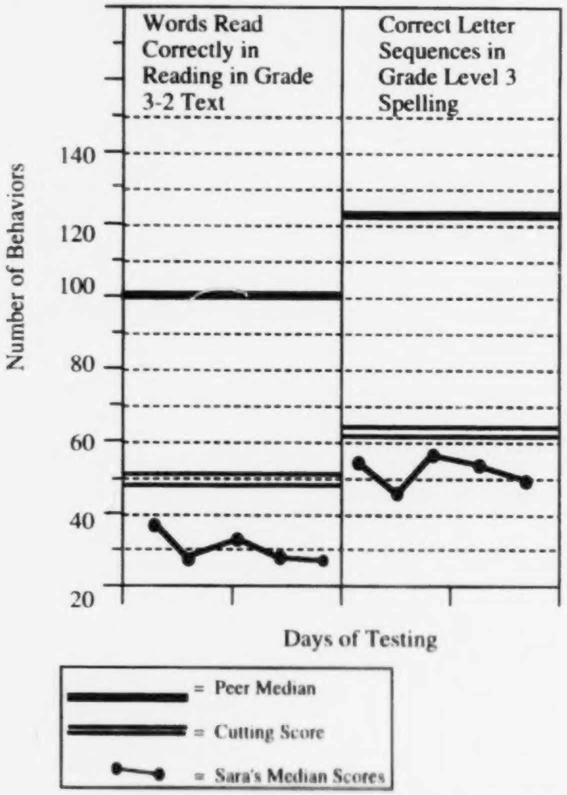
Once a problem is identified, a Problem Certification decision must be made. The major activity is to determine the magnitude or severity of the problem. As described in Table 1, Problem Certification is conceptualized as determining whether the difference between actual and expected performance is *serious* enough that a Multi-disciplinary Team (MDT) decides that it is unlikely that the academic problem will be resolved with general education resources alone. Once the magnitude of the discrepancy is known and the MDT decides that it is important, the team considers what resources may be available to resolve the problem (e.g., Chapter I, peer tutoring, special education). If the MDT decides that the student needs special education to succeed, eligibility is determined, assuming that procedural state and federal requirements are met (Shinn & Hubbard, 1992).

The Problem Certification process begins by conducting a Survey-Level Assessment using CBM for each academic area in which a problem has been identified. In a Survey-Level Assessment, the student is tested in successively lower levels in the curriculum sequence. For example, in Sara's school district's curriculum, there were two levels of third-grade text (3–2, 3–1), two levels of second-grade text (2–2, 2–1), and three levels of first-grade text, exclusive of preprimers. The data from Level 3–2 were obtained already during Problem Identification so there was no need to repeat that testing. Sara was tested using a minimum of three randomly selected passages in each book, beginning with Level 3–1 until the level was reached in which she performed successfully. The Survey-Level Assessment was completed in one testing session of about 20 to 30 minutes. The difference between her grade placement and the level of the curriculum in which she could be defined as *successful* would indicate the magnitude of the problem. The results of Sara's Survey-Level Assessment are presented in Table 3.

Success can be operationalized in one of two ways, by using (a) instructional placement standards or (b) normative scores. The use of instructional placement standards requires that a set of criteria is used to determine which level of the curriculum appears to be best for purposes of instruction. For example, a standard recommended for reading when first- or second-grade levels are considered and students are to receive teacher-led instruction is that students are placed in the highest level in which they read between 40 to 60 words correctly per minute. Students also must have high accuracy, about 90% to 95% or 4 to 6 errors per minute. For third- through sixth-grade reading curriculum, students are placed in highest level in which they read between 70 and 100 words correctly per minute. A higher fluency standard is required because of the increased cognitive complexity of the reading materials. Again, students must have very high reading accuracy.

These reading instructional placement standards are represented in Figure 3 to facilitate communication. The placement standards are marked by the

FIGURE 2. Results of Sara's problem-identification testing in Gradd 3 reading and spelling probes compared to same-grade peers.



dark bands. Sara's scores relative to the bands also are displayed. Clearly, her reading performance in third- and second-grade levels of the curriculum is too low for her to be considered successful in that material. The highest level of the curriculum in which she meets the instructional standards is the Level 1–2 book. By comparing her expected grade placement, if she were considered a typical student, to her recommended instructional placement, it could be concluded that she is approximately 2 years behind according to the publisher's scope-and-sequence chart.

The second approach to operationalizing the severity of a problem is to determine the student's *normative score*. This index is obtained when the tested student's percentile rank score in material from a particular curriculum level falls in the average range of the local norm at that grade. Sara's percentile rank reading scores are also included in Table 3. For making Problem-Certification decisions, this local norm is based on a sufficient sample size to ensure stable, representative norms such as school district norms of at least 100 students per grade. The definition of "average" must be agreed upon in advance. Some districts have used a conventional definition of performance between the 25th and 75th percentiles as average. Other districts have used a score from the 16th to 84th percentile (equal to plus or minus one standard deviation) as the definition of average. The latter definition was used in Sara's case. Sara earned reading scores that are clearly outside the normative range for students in third and second grade. Sara's score in reading first-grade material was better than most first graders who enter school as nonreaders (Shinn, 1988).

To facilitate decision making, the Survey-Level Assessment information can be graphed relative to the range of typical students reading scores in first- through fifth-grade-level materials at times similar to testing. Sara's scores are presented graphically this way in Figure 4.

To make Problem-Certification decisions, school leaders must establish a percentile-rank cutting score below which students can be considered for special education eligibility. One cutting score that has been used with some success is performance below the 16th percentile of students one grade below current placement. See Shinn (1989) for more detail on this topic. Using this criterion it was determined that Sara

TABLE 3
Reading Survey-Level Assessment for Sara with Curriculum Level and Performance Relative to Local Norms

Level of Ginn Curriculum	Sara's Median Performance	Grade-Level Peer Performance	Sara's Percentile Rank
3–2	27	100	2nd
3–1	27	NA	NA
2–2	32	NA	NA
2–1	37		15
1–3	49	NA	NA
1–2	55	**	**

Note. * = Local norms were developed only from 1 level of curriculum per grade level. Therefore, no norms are available for these curriculum levels.

**No first-grade students were tested in the Fall because most students entered with limited reading skills.

could be eligible because she performed at the 14th percentile in second-grade material compared to second-graders.

The second part of the Problem-Certification decision involves considering whether the student needs special education to benefit from their education. A student may not need special education services, even though they may meet the eligibility criterion (Rothstein, 1990; Shinn & Hubbard, 1992). Need is determined by examining the student's instructional needs in the context of resources available in general education that may resolve the problem. Only after considering Sara's reading performance in the context of the adequacy of her general education instructional environment, her behavior in that environment, other instructional opportunities available (e.g., lower reading group, peer tutoring), previous achievement, health, social and family factors, did the MDT determine that it was unlikely that the problem would be resolved with general education resources alone.

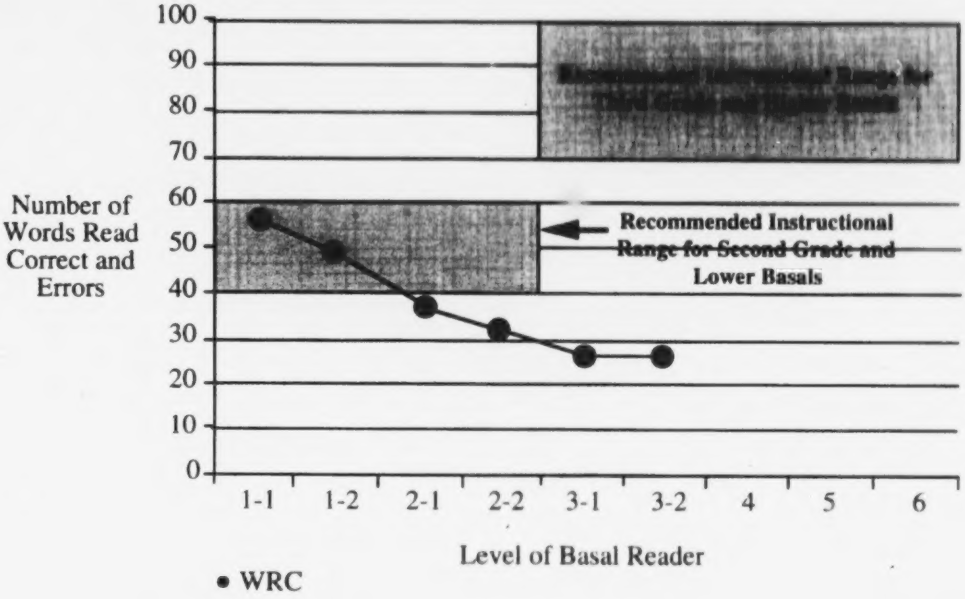
Exploring Solutions

If schools are well practiced in any assessment activity, it is in testing for purposes of determining special education eligibility. Thus far, this chapter has described the use of a Problem-Solving model to provide a needs-based assessment approach that arguably works as well or better than conventional eligibility determination activities (Shinn, 1989). Unfortunately, schools are less well practiced and proficient in assessing students for the purposes of intervention planning intervention and evaluation. Using CBM within a Problem-Solving model can remedy this situation when students have academic problems. The Problem-Solving model makes explicit the importance of assessment for intervention planning during the Exploring-Solutions decision. Using CBM in a Problem-Solving model allows a linkage between assessment for eligibility purposes and intervention planning. As will be seen later in this chapter, the use of CBM also allows linkages between assessment for eligibility purposes and intervention planning to intervention evaluation.

As presented in Table 1, the purpose of Exploring Solutions is three-fold, to specify (a) the data-based goals of the intervention, (b) the *content* of the intervention or "what to teach," and (c) the *means* to deliver the intervention or "how to teach." CBM is most useful for the goal-setting component of Exploring Solutions. Although not useless for intervention planning, other CBA models are more suitable for determining intervention components and processes. Howell's Curriculum-Based Evaluation (e.g., Howell, Fox, & Morehead, 1993) is especially well-suited for making intervention planning decisions.

General goal-setting approach. CBM's linkage between eligibility assessment and intervention planning begins by using the data collected during Problem Identification and Problem Certification to *develop intervention goals* for the student (Fuchs & Shinn, 1989). The mechanism for goal setting is the annual goal of a student's Individualized Education plan (IEP). The basic *idea* is simple and works much like conventional practice; annual goals are based on identifying "where the student is now" and where the IEP team would like the student to perform in 1 year, if the intervention is successful. What differs from conventional practice is that when using CBM, it can be determined more directly "where the student is." This decision is not made using grade-equivalent scores from tests that may not measure a student's curricular skills. Instead, the decision is made by testing students *directly* in the curriculum they would be expected to learn in general education classrooms. Similarly, expectations about future performance are not gross extrapolations from a test's grade equivalent scores but are based on Survey-Level Assessment in curriculum-level materials a student would be expected to show mastery of in 1 year. This process can

FIGURE 3. Reading survey-level results for Sara.



be illustrated using the case study. Sara's Survey-Level Assessment data showed her as "successful" in the Grade 1, Level 2 general education reading book. In 1 year, according to the publisher's scope-and-sequence, typical students would be expected to perform proficiently in Level 2 of the Grade 2 basal. The IEP team individualizes the annual goal by discussing the expectations for individual students. If the IEP team wanted to write a goal that facilitated Sara's "catching up" (i.e., reducing the discrepancy), they may want her to perform proficiently in a third-grade or even fourth-grade level of the basal series in 1 year. In Sara's case, the IEP team decided that they would consider the special education program to be successful if she performed proficiently in the Level 3–2 general education basal reader in 1 year.

Writing the annual goal. Annual IEP goals based on CBM data are written in the format of traditional behavioral objectives, and consist of a *behavior* to be measured, *conditions* for attainment, and *criterion* for success. The basic format in reading, math, written expression, and spelling is illustrated in Table 4.

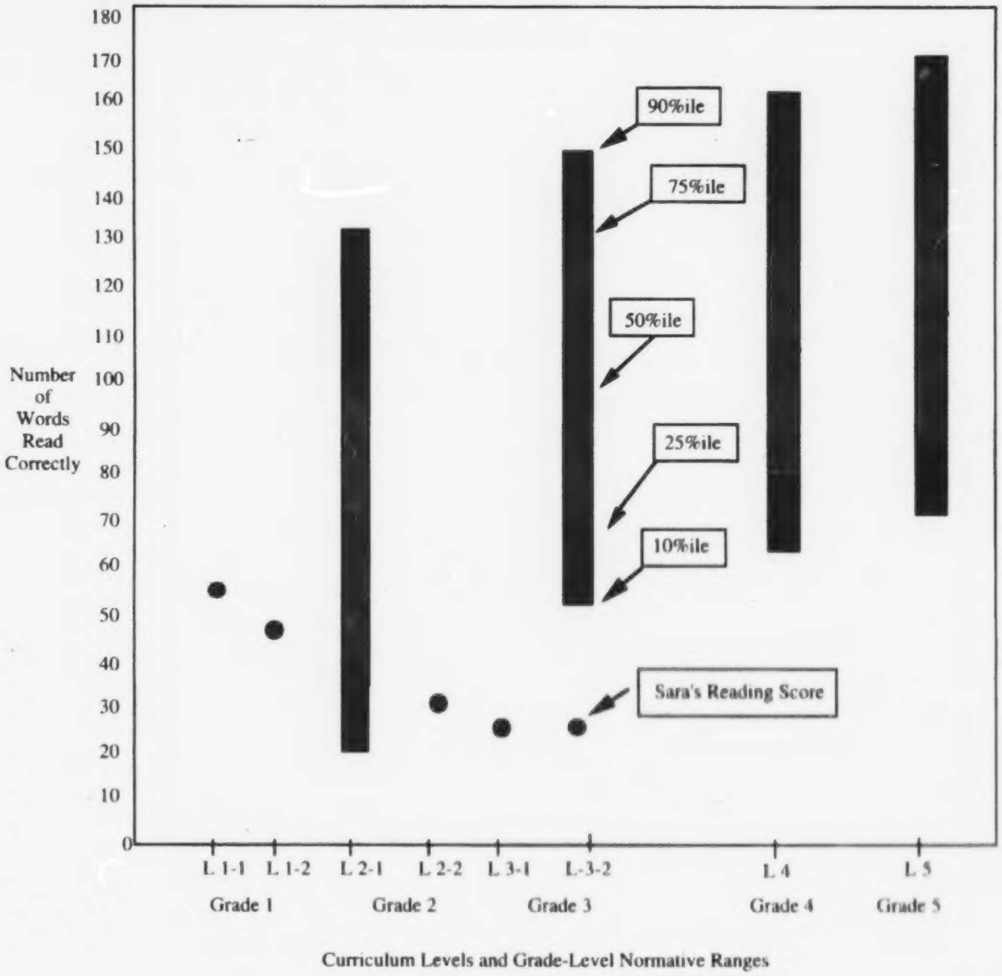
CBM IEP goals use a long-term approach to goal setting. In a long-term goal approach, measurement of progress towards the goal is designed to answer the question, "Is the student becoming more proficient in reading, math, writing, or spelling in the general education curriculum?" This approach has an advantage over most common long-term goals (e.g., "Will improve 1 year in spelling") in that they are observable, measurable, and are tied directly to a validated way of *formative evaluation*. With formative evaluation, effective interventions identified during instruction are maintained; ineffective interventions are modified.

This long-term goal approach also avoids the numerous difficulties with short-term measurement (e.g., "Will master multiplication facts with 80% accuracy) that are problematic because they are tied to specific units or small skills within a curriculum. The advantages of using CBM and a long-term goal approach are discussed in more detail in Fuchs, this volume, and in Fuchs (1993) and Fuchs and Deno (1991).

The goal-setting process begins with identifying the academic area in which the goal is to be written. Once the academic area is specified, the dynamic indicator for that content becomes the behavior to measure. Therefore, because Sara requires an annual goal in reading, the IEP team knows that the behavior component of the goal is oral reading.

The second step is establishing the goal's *conditions*. The *time-frame* is the time at which the goal is expected to be accomplished. In Sara's school system, all IEP goals expired on their anniversary data, 1 year from the time of writing. Therefore, Sara's annual goal would begin "*In 36 weeks (1 academic year), . . .*" The next task is *specification of the level of curriculum* at which the student will be expected to perform proficiently in 1 year. This task requires knowledge of the general education curriculum scope-and-sequence, a judgment of how much is expected to be accomplished, and the ramifications on how the problem is defined. For example, writing an annual goal so that a special education student is ex-

FIGURE 4. Results of Sara's survey-level assessment in reading, comparing her performance to same- and other-grade general education students.



pected to make less than 1 year's growth in general education curriculum is constructing an intervention that will leave a student further behind general education peers *and* the intervention would still be considered effective! Writing an annual goal so that a special education student is expected to make more than 1 year's growth in general education curriculum is constructing an intervention that, if successful, will make the student's skills more like general education peers. See Fuchs and Shinn (1989) for more detail on this topic. Because Sara's IEP team specified Level 3–2 as the annual goal material, when combined with the time frame and the behavior, her goal so far would read as follows: "*When given a randomly selected passage from Level 3–2 of the ABC Curriculum, Sara will read aloud . . .*"

The final task in setting annual goals requires specification of a *criterion for performance.* The question for Sara is "How well do we want her to read the Level 3–2 basal, if her intervention program is to be considered successful?" Two broad approaches can be used to identify a criterion for success, with or without local norms. When local norms are available, the IEP team can use the level of performance of typical students in the level of the curriculum identified in the conditions section as the criterion. For example, in Sara's case, because the IEP team distinguished book 3–2 as the level of the curriculum they desired in 1 year, they could expect that Sara read it as well as the typical third-grader in the Fall or 100 words read correctly. Alternatively, they could expect that Sara would read the Level 3–2 reader as well as an end-of-year third grader or 133 words read correctly.

In the absence of local norms, other strategies may be used to identify a criterion for success on the

TABLE 4
Basic Format for CBM Annual IEP Goals in Reading, Math, Written Expression, and Spelling

Academic Area	Conditions	Behavior	Criterion
Reading	In *(number of weeks until annual review),* when given a randomly selected passage from *(level and name of reading series),*	Student will read aloud	at *(number of words per minute correct / # of errors).*
Math	In *(number of weeks until annual review),* when given a randomly selected problem from *(level and name of math series),* for two minutes,	Student will write	*(Number of correct digits).*
Written Expression	In *(number of weeks until annual review),* when given a story starter or topic sentence and 3 minutes in which to write,	Student will write	A total of *(number of words or letter sequences).*
Spelling	In *(number of weeks until annual review),* when dictated randomly selected words from *(level and name of spelling series),* for 2 minutes	Student will write	*(Number of correct letter sequences).*

Note. From "Writing CBM IEP Objectives" (p. 136) by L. S. Fuchs and M. R. Shinn, 1989. In M. R. Shinn (Ed.), *Curriculum-Based Measurement: Assessing special services for children.* New York: Guilford Press. Copyright 199 by the Guilford Press. Reprinted by permission.

annual goal. *Expert judgment* requires that IEP teams use an organizer that the student be expected to perform at a significantly higher level in a more difficult level of the curriculum in 1 year. The use of *instructional placement standards* is another strategy for goal setting without local norms. It is based on setting the criterion for success at a level of performance such that the curriculum is appropriate for instructional purposes for the student in 1 year. In reading, for example, the IEP team could use the instructional placement standards given earlier in the chapter. Using this approach in Sara's case, the criterion for success could be that, in 1 year, she would read a randomly selected passage from Level 3–2 between 70 to 100 words correctly. It is important that a more specific value is used rather than a range. If a high level of proficiency is expected, then the IEP team could select the upper end of the range (100 words read correctly) as the criterion for success. If a lower level of proficiency is satisfactory, then the IEP team could select the lower end of the range (e.g., 75 words read correctly). See Fuchs (this volume) and Fuchs and Shinn (1989) for more information on writing annual goals using CBM.

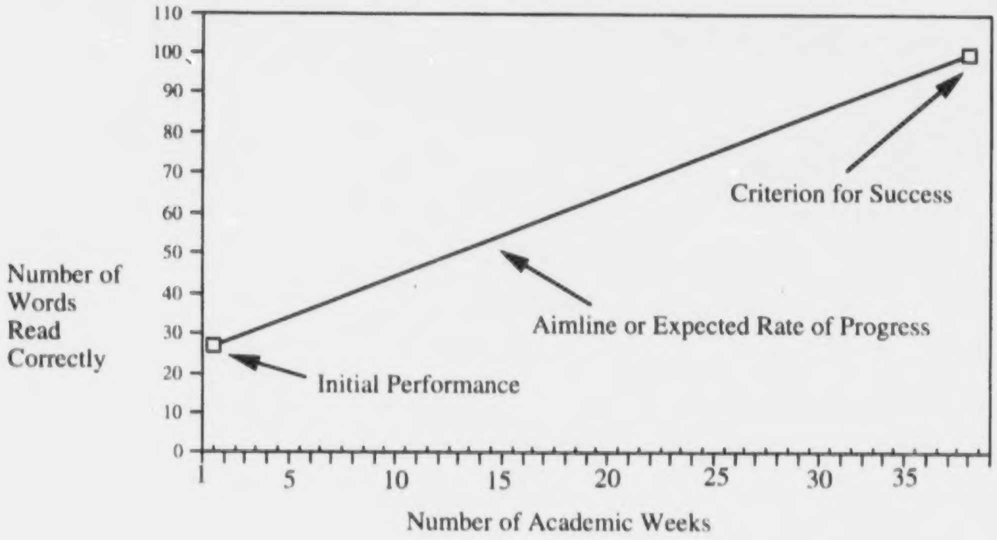
The actual IEP annual goal written by Sara's IEP team was as follows: *When given a randomly selected passage from Level 3–2 of the ABC Curriculum, Sara will read aloud 100 words correctly per minute.* The team also added an accuracy criterion that she would read a randomly selected passage with 5 or fewer errors (approximately 95% accuracy). This goal was based on a rationale to have Sara proficient in an end-of-third-grade reader by the time she was in fourth grade. The team considered reading at 100 words correctly, the median level of third graders in that level in the Fall, as proficient.

Evaluating Solutions

The use of CBM Survey-Level Assessment data to write annual IEP goals links assessment for eligibility decision making to intervention planning. The use of CBM IEP goals links intervention planning to intervention evaluation by providing a standard for determining intervention effectiveness. As presented in Table 1, the purpose of Evaluating Solutions is to monitor student progress toward IEP goals and determine an intervention's effectiveness.

As with other decisions in the Problem-Solving model shown earlier, the annual goal can be represented graphically as shown in Figure 5 to clarify communication of expectations. In the figure, her initial Survey-Level data in Level 3–2, the annual goal material, represents her current performance. The intersection of the criterion for success (100 words read correctly) and the goal date (36 weeks) forms her *aim.* The line drawn from her current perfor-

FIGURE 5. Graphic display of Sara's IEP goal translated into expected rate of student progress.



mance to her aim forms her aimline or *expected rate of progress*. By comparing her actual rate of progress, the *trendline*, determined by collected samples of her reading from Level 3–2 over time, with her expected rate of progress, decision can be made about treatment effectiveness and the need for program modification. When the actual rate of progress exceeds the expected rate of progress, the student's goal is raised. When the actual rate of progress is below the expected rate of progress, the student's intervention program is changed. See L. Fuchs (this volume) and the work of Lynn and Douglas Fuchs for more information on this topic.

Progress monitoring data usually are collected once or twice per week by a special education teacher delivering the intervention or via a microcomputer (Fuchs, 1988; Fuchs, Hamlett, & Fuchs, 1990). In reading, students read one probe each testing occasion. Testing items are selected from a pool that represents the domain of *all* the items from the goal level of the curriculum. With Sara, this would represent a sample from all passages in the Level 3–2 basal reader. Probes are created by randomly selecting subsets of items from this large pool and student progress is measured repeatedly on these probes. This process produces a set of parallel-form CBM probes with known technical adequacy.

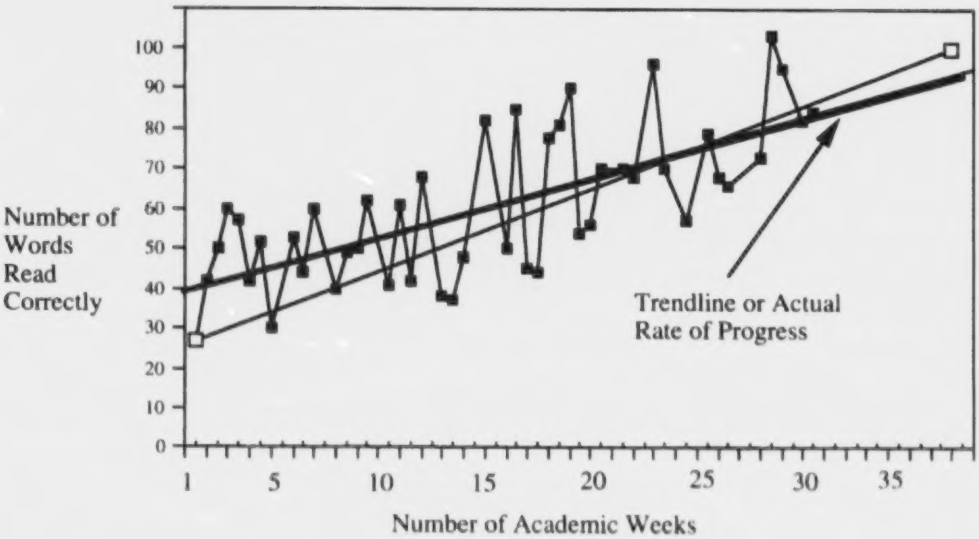
The results of testing Sara one to two times per week using randomly selected reading probes from Level 3–2 are shown in Figure 6. The data are plotted soon after testing on an equal interval graph. A minimum of 10 data points are suggested before a reliable decision can be made about the effectiveness of an intervention program (Good & Shinn, 1990). On Sara's graph, after the first 10 data points, it is clear that she is meeting or exceeding her expected rate of progress; 9 of the 10 data points are above the aimline. This is a good indication that the instructional intervention is effective and should be maintained. As the school year goes on, Sara's teacher continued to evaluate her progress routinely. At the end of the academic year, she had been tested 47 times during the 30-week-period. Her overall rate of progress, the trendline, is represented by the heavy black line that is calculated by drawing an ordinary least squares regression line through all the data. The trendline corresponds closely to the slope of the aimline, indicating an intervention program that is effective.

As mentioned earlier in the chapter, when the effects of instructional interventions are examined systematically and continuously, educators can make data-based decisions about whether to maintain or change interventions. Students need not receive instructional programs that do not meet their needs for long periods of time. Unsuccessful interventions can be changed to better meet students' needs. Educators need not discard or modify programs that may be working. The net result is that student achievement outcomes are improved significantly (Fuchs, Deno, & Mirkin, 1984; Fuchs & Fuchs, 1986).

Problem Solution

It can be argued persuasively that the kinds of testing activities that characterize long-term decisions about students' educational needs (e.g., annual reviews or special education exit) are little more than psychometric superstitious behavior. Annual reviews rely heavily on published achievements tests that

FIGURE 6. Graphic display of Sara's rate of progress relative to her IEP goal.



were not designed to evaluate the progress of individual students (Carver, 1974; Marston, 1989). Special education exit decisions occur so rarely that part of the problem must be related to measurement of outcomes. It is estimated that no more than 2% of special education students are exited each year (Fuchs, Fuchs, & Fernstrom, 1993). However, considerable numbers of these students have academic skills equal to those of general education students. For example, it has been demonstrated that in at least three school districts, 30% to 40% of special education students served more than 2 years in a pull-out program with an IEP objective in reading yet read as well or better than other low-performing readers in their general education classroom (Shinn, Baker, Habedank, & Good, 1993; Shinn, Habedank, Rodden-Nord, & Knutson, 1993). These students had not been considered for exiting special education.

A Problem-Solving model resolves some problems in determining students' long-term needs and the appropriateness of continued special education services. As presented in Table 1, Problem Solution decisions are tied conceptually to the assessment activities that defined the problem in the first place: Is there *still* a discrepancy between what is expected for the student and how the student performs? Procedurally, the discrepancy is measured again and is augmented by study of the special education student's rate of progress towards their IEP annual goal.

The logical time to make Problem-Solution decisions is during the periodic and annual reviews required by law (Rothstein, 1990). To date, periodic reviews rely heavily on informal subjective opinions of the teacher with responsibility for the intervention plan. Rarely are data collected or analyzed systematically specifically for this purpose. Annual review decisions usually are more structured and are oriented around the collection of student outcome information. CBM data can be collected efficiently at both periodic and annual reviews.

Periodic reviews. Periodic reviews are conducted with two pieces of CBM assessment data, the student progress graph and new peer-referenced testing results. These data are used to answer the questions: Is the student making progress? And if so, is the progress "important?" The first question is answered by examining the student's graph showing the rate of progress toward the IEP annual goal. As in making Evaluating-Solutions decisions, intervention effectiveness is determined by comparing the student's trendline to the aimline. If the trendline exceeds the aimline, two explanations are possible: (a) the intervention is effective; or (b) the annual goal is too low. If the trendline is below the aimline, two other explanations are possible: (a) the intervention program may be ineffective and need to be changed, or (b) the student's annual goal may be too high.

The second question about the importance of the student progress helps separate out issues of intervention effectiveness and goal appropriateness. Student change is defined as "important" if it results in *reduced discrepancies*. Data to make this decision is collected by testing the special education student in a norm-referenced manner as in Problem Identification. Again, random samples of the curriculum from the student's expected grade placement are used for testing. However, unlike Problem Identification, this testing takes place in one sitting rather than by collecting repeated samples over time. The student's

TABLE 5
Periodic and Annual Review of Reading Assessment as Part of Problem-Solution Decisions for Sara in Reading

Level of Curriculum	*Sara's Fall Median WRC	*Sara's Fall Percentile	**Sara's Winter Median WRC	Sara's Winter Percentile	*Sara's Spring Median WRC	*Sara's Spring Percentile
3–2	27	2nd	53	4th	69	6th

*Based on SSurvey-Level Assessment
**Peer-Referenced Testing Compared to Same Grade-Students Only

scores are compared to same-grade peers, using the type of summary metric that was employed in Problem Identification.

Changes in discrepancy ratios or percentile ranks are noted. Reduced discrepancies indicate that the special education student has made meaningful, important growth. When combined with the student IEP graph information, the change in relative standing allows for an evaluation of a student's overall special education program, including intervention effectiveness and goal appropriateness. The use of these types of data is illustrated in the case study. A periodic review was conducted with Sara the first trimester after her special education certification (Winter), approximately 10 weeks after her special education placement. Her IEP progress graph at Week 10 showed her consistently scoring at or above her aimline (see Figure 6). Sara also was tested using three randomly selected passages from the same level of the reading series as her initial Problem Identification testing. This process took less than 10 minutes. Her scores, summarized in percentile ranks, are shown in Table 5. The number of words she read correctly increased to 52 and the magnitude of the discrepancy decreased from performance at the 2nd percentile compared to same-grade peers to the 4th percentile. Both pieces of data indicate that the progress she is making towards her IEP goal is educationally meaningful; she is reducing the reading skill discrepancy. If she were achieving her IEP goal, but not reducing the discrepancy, one could conclude that perhaps the IEP goal was not ambitious enough to result in real improvement. Conversely, if she were not making progress towards her IEP goal, but was reducing the peer discrepancy, it could be concluded that her goal was too ambitious and should be lowered.

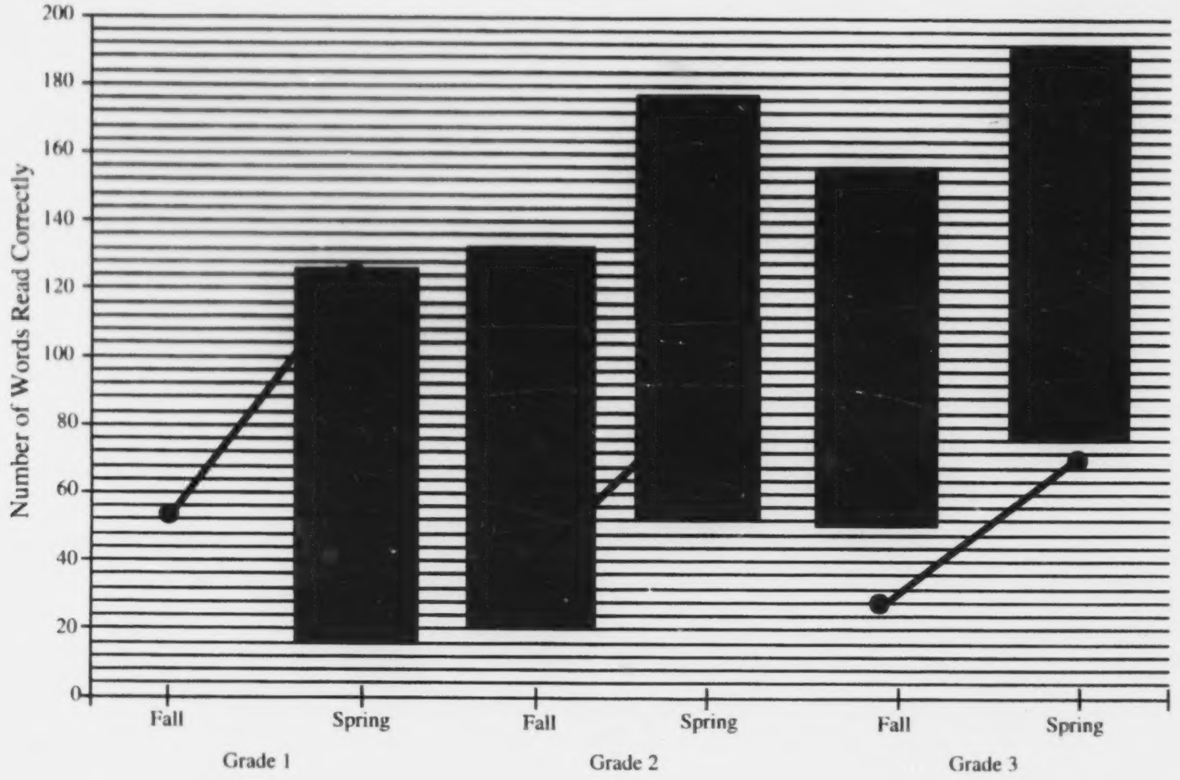
Annual reviews. The annual review process is a more in-depth assessment of a student's skill level and rates of progress. Again, progress towards the IEP annual goal is investigated by comparing actual-versus-expected student progress on the student performance graph. As can be seen in Sara's graph, at Week 30 when the annual review was conducted her actual rate of progress paralleled her expected rate. Overall, the annual review team believed the special education intervention to be effective and considered her to have attained the annual goal. Some concern was expressed over the current effectiveness of the program, however, as 7 of the last 10 data points fell below the aimline.

For annual review, more information is collected on the current severity of the problem with a new Survey-Level Assessment identical to the one conducted during Problem Certification. Not only are the Survey-Level Assessment data used to determine problem severity, but they are also used to write the annual goal for the next year. The results of Sara's annual review Survey-Level Assessment are also presented in Table 5. Sara's number of words read correctly improved again in third-grade material and the discrepancy from peers was reduced as she improved from the 4th to the 6th percentile. Her reading skills also improved significantly from Fall in all levels of the general education reading series.

Annual review Survey-Level Assessment results can be displayed graphically to show the growth relative to norm groups as shown in Figure 7. With adequate progress towards the IEP goal and a reduced discrepancy, the team considered the intervention successful and discussed Sara's continued *need* for the intervention.

A key decision in Problem Solution is determining when additional resources such as special education are no longer needed. In a Problem-Solving model, this decision is reached when the discrepancy is no longer important; that is, the special education student's skills are within the range of students in general education classrooms. In this instance, stu-

FIGURE 7. Fall and Spring survey-level assessment results for annual reviews.



dents may be exited from special education and returned for instruction in less restrictive environments. For more detail on this topic, see Allen (1989) and Shinn, Habedank, Rodden-Nord, and Knutson (1993). Use of CBM to assist in making special education exit decisions resulted in an increase from 4% of special education students exited on an annual basis to 20% (Marston & Magnusson, 1988).

SUMMARY

Curriculum-Based Measurement (CBM) is a consistent and continuous measurement system that was designed to function as DIBS, dynamic indicators of basic skills. These DIBS are to be used as educational thermometers, tools to (a) identify an academic problem and (b) decide whether the intervention for that problem is effective. CBM is inextricably tied to a Problem-Solving model in which data are used to guide decision making. Decisions are tied to general education curricula and often to how typical students perform in that curriculum. However, the critical feature that defines CBM is the collection of data on repeated standard tasks for *individual* students. When used to evaluate and modify instructional intervention programs for individual students, research findings consistently have found significantly improved outcomes. Programs for special education students are improved by allowing for validation and modification of individual interventions, better IEPs can be written, and assessment can be linked to intervention.

Because most CBM data are collected by trained special education and general education teachers, with consultation and supervision by school psychologists, the special education eligibility testing load for school psychologists can be reduced substantially. This reduction in testing load can be used to increase the amount of time school psychologists spend in indirect and direct service provision to all students in America's schools. One of my mentors once paraphrased an old saying, commenting that "school psychologists are trained to admire (i.e., identify) problems, not solve them." In more ways than one, CBM and its use in a Problem-Solving model allows for this conception of school psychology practice to change.

AUTHOR NOTES

The development of this chapter was supported, in part, by Grant No. 8029D80051-92 from the U.S. Department of Education, Special Education Programs, to provide leadership training in curriculum-based assessment and by Grant No. H023C10151 from the

U.S. Department of Education, Office of Special Education Research, to conduct research in using Curriculum-Based Measurement to facilitate reintegration of students with mild disabilities into general education classrooms. The views expressed within this chapter are not necessarily those of the U.S. Department of Education.

Deno, S. L. (1986). Formative evaluation of individual programs: A new role for school psychologists. *School Psychology Review, 15,* 358–374.
In this article, problems associated with traditional assessment practices and functions of school psychologists are identified and a new role for school psychologists is proposed. The use of CBM formative evaluation is presented as a methodology that permits school psychologists to provide assessment information that is relevant in determining the effectiveness of educational interventions.

Deno, S. L. (1991). Individual differences and individual difference: The essential difference of special education. *The Journal of Special Education, 24*(2), 160–173.
In this article, the current aptitude-treatment interaction (ATI) instructional technology is examined and determined to be insufficiently responsive to individual differences of students. Instead, a formative evaluation model is proposed as an idiographic approach to building more effective programs for individual students. In this model, aptitude differences at the outset of a program are de-emphasized and methodology for tailoring programs to individual students during instruction becomes the focus.

Fuchs, L. S. (1986). Monitoring progress among mildly handicapped pupils: Review of current practice and research. *Remedial and Special Education, 7,* 5–12.
A review of research is presented in this article on the use of formative evaluation to improve instructional programs for mildly handicapped students. Critical issues discussed regarding this methodology for monitoring student progress are focus of measurement, frequency of measurement, data display, and data-utilization methods.

Fuchs, L. S., & Deno, S. L. (1991). Paradigmatic distinctions between instructionally relevant measurement models. *Exceptional Children, 58,* 232–243.
A comparison of the advantages and disadvantages of specific subskill mastery measurement (short-term goal approach) and general outcome measurement (long-term goal approach) progress monitoring is presented. General outcome measurement emerges as the most advantageous method for monitoring student progress. A case study is presented to illustrate the differences between approaches.

Kramer, J. (Ed.). (1993). *Curriculum-based measurement.* Lincoln, NE: Buros Institute of Mental Measurements.
In this book CBM is presented from the perspectives of a variety of scholars whose efforts have, in large part, defined the CBM approach to problem-solving assessment (Deno, Tindal, L. Fuchs, Lentz, Kramer, Shapiro, Shinn, & Good). CBM is defined, reviewed along with other assessment techniques that fall under the category of curriculum-based assessment, and presented as a method for enhancing instruction and student achievement. A prognosis for its future is discussed.

McKiggen, M., & Shinn, M. R. (1993). *CBM and problem-solving assessment: A self-instruction course.* Eugene, OR: University of Oregon School Psychology Program.
This continuing professional development (CPD) self-instruction course was designed for and researched with individual school psychology practitioners. Reading materials include Shinn (1989; see this annotated bibliography), a CBM skill-building workbook developed at the University of Oregon, and eight additional recently published articles. Course instructional materials include a six-unit syllabus, six unit quizzes, advance organizers for each assigned reading, and activity log forms to self- monitor progress through the course and maintain a record for CPD credits.

Shinn, M. R. (Ed.). (1989). *Curriculum-based measurement: Assessing special children.* New York: Guilford Press.

This book contains contributions of the work of the core-group of researchers and school practitioners (Deno, L. Fuchs, Marston, Shinn, Tindal, Allen) who developed and implemented CBM. Specific procedures for implementing CBM in school settings are detailed. General background information and conceptual issues surrounding the development and use of CBM as an alternative to traditional school psychology practice are also discussed.

Best Practices in Linking Assessment to Intervention

George M. Batsche
Howard M. Knoff
University of South Florida

OVERVIEW

Historical Perspective

With the 1975 passage of Public Law 94-142, the Education for All Handicapped Children Act, the number of practicing school psychologists grew dramatically. In fact, between 1970 and 1988, the number of school psychologists practicing in public schools quadrupled. Fagan (1988) identified this era (1970–present) as the "thoroughbred years." A review of the early history of school psychology indicates that "testing" was the primary function of those professionals identified as school psychologists. In the early 1970s, school psychologists began to add consultation, intervention, and organizational development activities to the existing assessment functions. However, the passage of Public Law 94-142 in 1975 resulted in an emphasis on the role of testing once again. The greatly increased number of school psychologists employed by school districts at that time were employed primarily to identify children and youth eligible to receive special education services.

P.L. 94-142 focused on the identification and placement of students with disabilities. As such, criteria were established for each of the handicapping conditions recognized in the act. School personnel were responsible for conducting assessments to determine the extent to which a student met the criteria for a handicapping condition and was eligible for special services. Because testing was, in and of itself, a required activity for determining eligibility for special programs, there was little or no pressure (from consumers or the profession) to expect more from the assessment process than an eligibility recommendation. The process of assessment for special education came under intense scrutiny, however, when litigation began over issues related to who (student demographics) was being placed (and more recently not placed) in special education. The *Larry P. versus Riles* case is but one example of litigation focusing on the appropriateness of psychological and educational assessment. However, the focus of the litigation was on the appropriateness of assessment relative to the *identification* of students for special education, not on its relevance to intervention.

During the heyday in the rise of special education services, intervention was linked to assessment only through the selection of a special education program for a student, not in the development of specific intervention strategies. *The special education placement was the intervention.* The outcomes of assessment were evaluated in terms of the appropriateness of the *placement* decision. Therefore, school psychologists were evaluated by supervisors and school district personnel on the basis of the number of students assessed, the number of staffings (teacher/parent conferences) conducted, and the number of students placed in special education. In fact, in many states, school psychologists (as well as special education teachers and other support personnel) were (and still are) paid out of special education funds available based on the number of students placed in special programs.

After the first 10 years following the implementation of P.L. 94-142, the focus of special services began to shift from the "child-find" function of the act to the efficacy of special education services. A number of researchers began to question whether placement in special education classes benefitted students with disabilities (Kavale, 1990). In the mid 1980s, advocacy began to place pressure on the U.S. Department of Education to conduct efficacy studies of special education services. The first report (National Council on Disability's *The Education of Students with Disabilities: Where Do We Stand?*) on the effectiveness of P.L. 94-142 appeared in 1989. The results of the report were not encouraging and recommendations were made that had significant implications for the profession of school psychology. Specifically, the report questioned the appropriateness of assessment (e.g., norm-referenced) that did not lead to the development and evaluation of intervention programs.

In recent years, there has been an increased focus on the link between assessment and intervention both in psychology and education (Batsche, 1992; Nelson & Hayes, 1979; Nelson, Hayes, & Jarett, 1986; Shapiro, 1988). In addition, the *outcome-based* education movement within the school reform process has triggered a general call for accountability in all aspects of education, including the profession of school psychology. Within school psychology one aspect of the accountability issue relates to the extent to which assessment procedures developed for *diagnostic* and eligibility determination can be used to develop and evaluate effective interventions. This is a healthy debate and has resulted in an increased focus (practice, research, teaching) on the link between assessment and intervention. More importantly, this focus has improved services to all students, resulted in new technologies for linking assessment to intervention, and provided an increased trust and integrity in the services provided by school psychologists.

An entire generation of school psychologists were trained in response to the unmet service delivery needs of students that resulted from P.L. 94-142. Training focused primarily on developing the skills necessary to conduct valid assessments of students with special needs from diverse backgrounds and to relating assessment results to program eligibility. There was little training provided in the areas of *functional assessment*, intervention development, and evaluation of interventions. Even today, the primary focus of training in the area of assessment remains on traditional norm-referenced assessment as it relates to diagnosis and placement concerns. However, if effective intervention plans for students with developmental, behavioral, and academic difficulties are to be formulated, assessment must relate to the development and evaluation of interventions, not to the process of diagnosis. The relationship between diagnosis and treatment (aptitude by treatment interaction) is not well established in psychology and education. Therefore, the link between assessment and intervention cannot occur through a problem-solving process designed to categorize disabilities. The link must be forged by understanding the relationship between the students and their needs and the environment and its resources. This requires a different approach to problem solving than the traditional "test-staff-place" approach. More appropriately, it will require developing assessment procedures designed to answer specific questions that relate to the academic, developmental, and behavioral difficulties of a particular student.

This chapter will present an empirically supported model of linking assessment to intervention, basic considerations of that model, and best practices associated with its implementation.

BASIC CONSIDERATIONS

Definition and Purposes of Assessment

Assessment designed to determine eligibility, placement, and diagnosis is *administrative assessment*. Assessment designed to develop and evaluate interventions is *functional assessment*. The problem-solving and decision-making processes of each are discrete. Attempting to "link" administrative assessment strategies to the development and evaluation of interventions is problematic.

The assessment/intervention debate in school psychology has been fueled, perhaps unnecessarily, by confusion over definitions. First, some would believe that assessment and testing are interchangeable terms. Nothing is further from the truth. This misnomer has developed from assessment practices that have, historically, relied primarily on "testing" (IQ, achievement, visual motor, emotional/behavioral). Assessment in psychology and education occurs primarily through four domains: *review* of records provided by school and family personnel, *interview* of persons familiar with the referral concern and/or responsible for interventions, *observation* of the student in assessment-appropriate settings, and *testing* the student directly. Any or all of these domains of assessment are appropriate when they are consistent with and valid for the purpose for which the assessment is being conducted.

Mash and Terdal (1988) have identified four common purposes of assessment: (a) diagnosis, (b) prognosis, (c) treatment/intervention design, and (d) evaluation of treatment/intervention effectiveness. Although the purpose of this chapter is to discuss the link between assessment and intervention, it is important to understand the "link" between assessment in school psychology to both diagnosis and prognosis as well as to intervention.

This chapter's authors believe that the debate over linking assessment to intervention (specifically testing) has been confounded by attempts to force assessment practices designed to yield data necessary for placement decisions to also function to develop and evaluate intervention programs. Assessment in special education has been conducted primarily for the *administrative* purposes of determining if a student is eligible for a special program. A concrete example of this would be the use of an audiometer (and the subsequent audiogram) to determine if a student meets the criteria for a hearing loss to be eligible for special services. A parallel example would be the use of an IQ test to determine if a student met the IQ criteria for eligibility for a program for students with mental disabilities. Although using an IQ test as a valid measure of the "mental ability" component of a mental disabilities diagnosis certainly has been debated, such use is an accepted practice and an IQ test is considered an appropriate measure to use when rendering such a diagnosis (as current diagnostic criteria exist). However, the use of an IQ test to develop educational interventions and then to evaluate the effectiveness of those interventions would be challenged vociferously within the profession.

School psychologists have attempted to justify the use of traditional tests to develop and evaluate interventions for a number of reasons, including: (a) discomfort with and lack of training in functional assessment; (b) lack of time and resources to conduct functional assessment; and (c) lack of time and support to evaluate program effectiveness. Traditional diagnostic tests have their most defensible "link" with the process of classification, not intervention. Using assessment practices designed for administrative purposes for the development and evaluation of interventions will be challenged.

The concept of *prognosis* has received little attention in the school psychology literature. If one equates prognosis with the severity of a problem (less severe, better prognosis, more severe, poorer prognosis) then Gresham's definition of severity proves useful. Gresham defines the severity of a problem as its *resistance to intervention*. If one accepts this definition, then the only assessment practices linked to the concept of prognosis are those that measure intervention efficacy. Therefore, *functional* measures of behavioral, emotional, developmental, and academic progress are valid measures for assessing the prognosis of a student. Assessment procedures that can be used both to develop and evaluate intervention programs serve the *multiple* functions of being used to design interventions, to evaluate their effectiveness, and to provide data to parents and teachers.

Shapiro and Kratochwill (1988) indicate that assessment and intervention procedures can be linked in three ways: (a) through the design of the intervention program, (b) by linking the assessment to the environmental conditions of the individual student's behavior, and (c) through treatment evaluation for the purpose of modification. To link assessment to intervention design, the school psychologist must develop hypotheses that relate (or link) the problem to potential causes. *Causes* are not defined here in the traditional medical model sense but rather are defined within the context of the student and his or her environment. Behavioral psychologists use the term, functional assessment, to denote this process. Taking Shapiro and Kratochwill's purposes of assessment further, one can only link assessment to environmental conditions if hypotheses can be developed regarding conditions under which the behavior will occur and can be assessed. The model of linking assessment to intervention presented in this chapter identifies six "conditions" that must be considered when developing an assessment plan for a student. These conditions are (a) child characteristics, (b) teacher characteristics, (c) peer characteristics, (d) curriculum issues, (e) school environment issues, and (f) family/community factors. Assessment practices that focus on the development of hypotheses that link the problem to the conditions under which the problem occurs, automatically provide a link with the desired intervention and the methods *R*eview, *I*nterview, *O*bserve, *T*est—RIOT) required to assess the effectiveness of that intervention.

Focus of Assessment

The first step in successfully linking assessment to intervention is the development and identification of *replacement behaviors*. The primary focus of problem solving using an assessment-to-intervention paradigm should begin with the identification of replacement behaviors, not problem behaviors.

Traditionally, assessment has focused on describing the referral *problem* within a particular theoretical framework (psychological, educational). Typically, interventions for behavior problems have focused on the reduction of inappropriate behaviors. This focus on the behavior problem is inappropriate for two reasons and provides a direct threat to the development of the assessment-to-intervention link. First, interventions that focus on the reduction of a behavior assume that the negative behavior will be replaced, automatically, by a prosocial behavior. This assumption may not be true. If a student has not learned the appropriate behavior (skill deficit), then simply eliminating the inappropriate behavior will not "teach" the appropriate one. Unless the reductive intervention is continued, the negative behavior will return as soon as conditions warrant. As the reductive intervention becomes successful in reducing the problem behavior, the teacher or parent will have fewer prompts to use the intervention. As the use of the intervention declines, the probability that the negative behavior will return increases. This is a common outcome of school-based interventions.

Second, interventions designed to reduce behaviors are not educative and do not draw on the teaching skills of school personnel. Interventions that *teach* behaviors have a number of advantages. First, they use the same teaching processes of modeling, role play, performance feedback, and transfer of training that teachers use every day to teach academic skills. Therefore, the "behavioral regularity" (Sarason, 1985) of the teacher remains intact and the number of new skills required to implement interventions are minimized. This increases the probability that the intervention will be implemented appropriately and willingly (treatment integrity and treatment acceptability). Second, as the interventions are implemented, the skills o the student are improved, not reduced. This reinforces the continued use of the intervention by reinforcing the teacher or parent for intervention implementation. Third, the implementation of educative intervention requires the identification of *replacement behaviors* and building toward a positive focus early in the assessment-to-intervention-linkage process.

The identification of replacement behaviors is critical to the implementation of a process that links functional assessment to effective interventions and, as the focus of assessment and intervention, accomplishes a number of goals. First, the replacement behavior is, by definition, the *outcome goal* of the intervention. Clarification of the replacement behavior with the referral agent (teacher, parent, or student) increases the probability that the intervention will be linked to clinically significant outcomes. Second, assessment focuses on the behavior which is the target of intervention and may be different from the original referral behavior. For example, if a student is constantly out of seat and bothering others, the replacement behavior may be the development of self-instructional behaviors related to self-control rather than simply reinforcement and reductive strategies for "staying in the seat." Assessment will focus on the presence or absence of the skills necessary to develop self-control (such as self-monitoring and self-instructional strategies) and not necessarily on the referral problem (out-of-seat behavior). The intervention might lead to self-instructional strategies combined with social skills training. The result, of course, will be a reduction of out-of-seat behavior (the teacher's concern). If the focus was an out-of-seat behavior, then the assessment might focus on a frequence counting or observation of out-of-seat behavior with interventions focused on reinforcement for in-seat behavior and a reductive strategy (such as time-out) for out-of-seat behavior. The focus on replacement behaviors from the beginning results in assessment for problem analysis that is the same as for intervention.

The Development of Model Linking Assessment to Interventions

Any model linking assessment to intervention must include (a) a link between the referral problem, its desired replacement behavior, and the conditions that support the problem and prevent its replacement; (b) the development of hypotheses, grounded in theory and practice, that are known to relate to the referral problem and the desired replacement behavior; (c) the development of predictions that enable the hypotheses to be evaluated through a multifaceted assessment process; (d) the use of assessment data to evaluate hypotheses rather than develop them; and (e) the use of assessment strategies that serve as the basis for intervention evaluation as well as program development.

Traditionally, school psychologists have administered a wide range of assessment procedures to students, teachers, and parents. The problem-solving focus of traditional assessment is to develop hypotheses from the data collected *after* assessment is complete. This results in information that describes student performance in terms of the test administered and the hypotheses used to develop the test. Using this approach, school psychologists often find themselves expected to interpret student performance and test results in areas about which they have little theoretical knowledge and few, if any, skills in the development of interventions. Examples of this might occur in the area of reading or childhood depression. School psychologists might be *trained* to administer tests of reading or tests that assess levels of depression. However, they may not *understand* the causes behind the reading problem or childhood depression and cannot develop hypotheses about why the problem is occurring or develop successful interventions.

The primary requirement for the use of the assessment-to-intervention model described in this chapter is the ability to develop hypotheses about the referral problem and the desired replacement behavior prior to the collection of assessment data. Assessment strategies are then selected based on the hypotheses developed and the referral questions asked. In this model, data are used to verify or nullify hypotheses developed *prior* to assessment rather than to develop hypotheses abut data *after* assessment. The use of this approach increases the probability that assessment strategies will be selected that assist in understanding the relationship between the problem, the replacement behavior, and the conditions under which they occur. Once this relationship is understood, the development of interventions (and their evaluation is the next logical step in the problem-solving process.

BEST PRACTICES IN LINKING ASSESSMENT TO INTERVENTION

The Referral Question Consultation (RQC) process (Batsche & Ullman, 1984; Batsche, 1984; Knoff & Batsche, 1991b) is an empirically based, generic, problem-solving model that can be used for specific academic and behavioral problems. More refined than the traditional generic problem-solving models that encourage problem identification, problem analysis, intervention, and evaluation steps (e.g., Curtis & Meyers, 1990), the RQC will require most school psychologists to make a paradigm shift as assessment truly is directly and functionally linked to intervention. The RQC process simply employs the scientific method in an empirically based, hypotheses-generating and -testing search for *why* a referred problem is occurring. The RQC process links functional assessment, focused on *explaining* and *confirming* why referred problems occur, with effective interventions for the purpose of facilitating the academic and social progress of referred students. Clearly, this is very different from the traditional refer-test-place approaches to psychoeducational assessment currently practiced in most of our schools (Gutkin & Conoley, 1990).

More specifically, the goal of the traditional psychoeducational assessment model is (a) to describe, often from a national, norm-referenced perspective, the referred problem in data-based (e.g., standard score) terms; (b) to investigate the extent to which a particular student may differ from same-age peers; and (c) to determine the referred student's eligibility, often using highly questionable criteria (especially in the case of learning disabilities, emotional disturbances, attention deficit disorders, and the like), for special education or other programs. Professionals who need to answer questions about the social and academic difficulties of students and to design effective interventions require a different approach to problem solving, one that goes beyond the eligibility-oriented decisions that result from standardized assessment. We feel that the RQC process fulfills this need.

The RQC method requires school professionals to comprehensively understand the types of social and academic problems referred to them. In too many instances, assessment teams rely on hypotheses derived from standardized assessment procedures, rather than on hypotheses based on (a) functional analyses of referral problems *in the environments where they occur* (e.g., Iwata, Vollmer, & Zarcone, 1990), and (b) reviews of empirical literature that relate to the referred problem. For example, there are multiple reasons why students experience reading, math, and written language problems or why they are aggressive, anxious, or withdrawn. Standardized psychoeducational assessment routinely answers the question "How much of a reading, math, or written expression problem exists?" but not "*What* potential conditions facilitate the existence of these problems?" Analogously, on a behavioral level, behavior rating scales and other personality assessment tools may indicate the type and level of a student's aggression, anxiety, or withdrawal, the teacher's or caregiver's perception of these difficulties, but not the reasons for their occurrence.

Expanding briefly, while three different students may exhibit the same frequency, duration, integrity, and typology of overt aggression, each student may be aggressing for a different reason. For example, one might be angry that his parents are getting divorced, another might be frustrated because academic work is too difficult, and the last might be reinforced for aggression by the gang members in his peer group. In each case, the strategic intervention will necessarily be different in that it focuses on the cause of the aggression (counseling, curriculum modification, group contingency procedures), taking the specific reason for the aggression into account. The RQC process provides the framework to validly assess "Why does this problem exist?" and links the answers to this question to procedures that lead to effective interventions. The method, however, does not independently generate the reason "why" a given problem exists. The *hypotheses* as to "why" a problem exists must be supplied by the professionals who are engaged in the RQC process as they functionally analyze the ecology and circumstances around the referred student and situation.

The RQC method is very rewarding for those individuals already aware of the potential reasons why a referred problem exists or willing to investigate those reasons. The RQC method is designed for the sole purpose of implementing effective interventions based on valid hypotheses that have been verified through functional assessment. It is not designed to provide additional information concerning special program eligibility or to diagnose children and adolescents. The authors believe that the processes necessary to determine program eligibility and those necessary to implement effective interventions are different. Each serves its own purpose well. As previously noted, problems arise, however, when one method is used to achieve the goals of the other.

The RQC Process

The RQC process typically involves any and all school professionals who interact with and might facilitate the problem-solving process relative to a referred student. It is assumed at the outset that all participants have expertise, each in their own professional area, and that the diversity of their perspectives will significantly enhance the problem-solving process and the search for reasons to explain a specific, referred behavior. After an individual student has been referred, the RQC process involves 10 interdependent steps:

1. *Review* all existing data available on the referred student and collect any additional background data as appropriate.

2. *Meet* with the referral source in a *consultative interview* to behaviorally define his or her initial concerns, to identify desired *replacement behaviors*, to identify the need for additional data to finalize the behavioral operationalization of these concerns, to informally test some initial hypotheses, and to determine the referral source's assessment goals and commitment to the RQC process.

3. *Develop hypotheses* to explain the initial concerns as behaviorally operationalized.

4. *Develop prediction statements* from the generated hypotheses to organize assessment strategies.

5. *Develop data-based referral questions* that will guide the assessment process and confirm or reject the generated hypotheses.

6. *Select multitrait, multimethod assessment procedures* that will specifically answer the referral questions and facilitate the link between assessment and intervention.

7. *Apply the assessment and background data* so as to answer the referral questions and to confirm or reject the generated hypotheses.

8. *Select and implement intervention strategies* consistent with those hypotheses that have been confirmed.

9. *Monitor and evaluate change* in the area of the initial concern to determine the impact of the intervention.

10. *Develop a written report* that documents the RQC process, the interventions tried, and the intervention outcomes as they relate to the resolution of the initial, referred concerns.

Review of the Data

When a multidisciplinary team or school psychologist receives a request for consultative services from a teacher, the first step in the RQC process is to review essential information about the referred student and to collect any additional background data that may be important to know before interviewing the teacher. The review of essential information typically centers around an analysis of four possible existing student areas or "folders": (a) the student's cumulative folder, (b) the administrative/discipline folder, (c) relevant teachers' academic work sample folders (student portfolios), and (d) the special education/remedial education (e.g., Chapter 1) folder. In addition to the information available in already-existing records and student folders, it may be time- and cost-efficient to collect other data from teachers and other sources prior to an initial consultation interview. This information may be collected through behavior checklists, behavior rating scales, ecological or developmental status surveys or questionnaires, or standardized inventories, and it may, for example, provide the answers to routine developmental status questions so that precious interview time can focus on areas more germane to the referral concerns. This information may facilitate a more accurate and in-depth behavioral or operationalization of the teacher's initial concerns, identify possible correlates of those concerns, identify possible student assets and strengths, generally prepare the school psychologist more thoroughly for the consultation interview and the teacher's (and others') perception of the referral problem, and provide content for hypothesis generation.

In all, a number of questions can be answered, even before the first consultative interview with the teacher, by reviewing existing student records and collecting rating scale and other information as appropriate. Among these questions are the following:

1. Is the student age-appropriate (young or old) for the grade?

2. Has the student been retained, received special services, or preschool services? How many schools has the student been in? How many school placement programs has the student experienced?

3. What has been the average yearly academic progress of the student?

4. Has the student had an unusual health history or have there been significant medical traumas or events in the student's life? Is the student currently taking medication? Is health or medication status related to the referral problem?

5. Are there documented effects of retention, special services, or other interventions on the student's academic or behavioral problems?

6. Has there been a documented history of behavior or disciplinary problems? If so, do behavior or disciplinary problems appear consistently over time?

7. What has the student's attendance record been over his or her academic career? Is there a relationship between attendance and the referred problem?

8. Are there documented family or developmental history factors that have contributed to any student problems?

9. What interventions have been tried with the student? What has been their effects?

10. What are the student's academic and social-emotional strengths from the perspective of teachers, parents, and other significant informants?

11. What are the student's academic and social-emotional weaknesses or problems from the perspective of teachers, parents, and other significant informants?

These last two questions can be answered most comprehensively, as noted previously, through the use of developmental scales and curricular scope and sequence charts,in the case of academic status, and behavior rating scales and objective personality assessment scales, in the case of social-emotional behavior. While school psychologists should ask teachers, they also should involve parents, students, and significant others so that (a) the broader ecology in which the referred child lives can be understood and (b) situation-specific versus more generalized academic and behavioral patterns can be discerned. While these data may be used and validated later during the multitrait, multimethod assessment process that focuses on hypothesis confirmation, the data collected from these tools, at this point in the RQC process, can only be considered teacher or parent perceptions.

The Consultative Interview

The consultative interview(s) involving those individuals referring and relevant to a specific child, is the most important activity in the RQC process. While the long-term impact of the consultation interview focuses on intervention planning and implementation, the interview has a number of goals as the second step of the RQC process:

1. To engage the teacher (and/or parents) in a comprehensive problem-solving consultation process such that they are committed to the process from beginning to end and to the service delivery directions that result from the process and fully understand (and feel) their importance to problem solving.

2. To obtain additional relevant information beyond that already collected during Step 1, Review of Data, and to integrate and apply all of the data to the next steps of the RQC process.

3. To clarify the initial concerns of the referral source, using all the data collected, resulting in a behavioral definition and operationalization of the behavior(s) of concern.

4. To identify replacement behaviors which will become the target of assessment and intervention.

5. To determine which interventions have already been attempted and to evaluate the treatment integrity and impact of those interventions.

6. To begin to generate tentative hypotheses that explain the clarified concern and to outline the remainder of the RQC assessment process for the consultee.

For the purpose of brevity, it is assumed that the consultative interview is done within a "best practices" context using effective consultation skills, methods, and processes (Gutkin & Curtis, 1990; Knoff, McKenna, & Riser, 1991). Pragmatically, then, the consultation interview addresses the following questions directly or indirectly:

1. To what extent can the referral source (e.g., the teacher) describe the referral concern (and other student liabilities) in behavioral terms, or is he or she only able to provide vague descriptions of concerns (e.g., "the child has a reading problem")?

2. What are the referred student's strengths across those domains relevant to the referral problem(s), across those domains that might be used in an intervention program for the referral problem, and across other domains that do not necessarily relate to the referral problem?

4. Where does the problem occur least often? Is the problem occurring more or less often than (a) last week, (b) last month, (c) the beginning of the year, (d) or at the onset of the problem? When did the problem behavior first occur? What is the teacher's preferred approach in solving the problem?

5. What is the function of the behavior for the student? for other students? for the teacher? What is the teacher's style, skill, and investment in dealing with the problem?

6. Is the problem a skill, performance, or self-management deficit for the referred student? Is the problem a skill, performance, or self-management deficit for the teacher?

7. How often can the behavior occur and still be tolerable for the teacher? How do other students in the setting behave and is their behavior acceptable/tolerable? If the student were unable to engage in the problem behavior, which other problem behaviors might occur as substitutes?

8. Which interventions have been tried before? What were the goals and characteristics of these interventions, how were they implemented, and what were the outcomes for the student and for the teacher, parents, and significant others?

9. What would motivate the teacher to work on this problem in the classroom setting? How would solving th problem behavior make the teacher's day easier? What is the teacher's commitment to work on the problem?

All of these questions can be expanded and individualized to the referred student, the referral problem, and the teacher, and some of these questions may be answered over the course of a number of consultation interview sessions. Nonetheless, all of these questions are asked (a) to clarify and behavioralize the consultee's initial concerns; (b) to identify the more positive or proactive behaviors needed to replace those deficit or maladaptive behaviors related to other initial concerns (called "replacement behaviors"); (c) to generate hypotheses that help to identify conditions under which the referral problem is occurring; and (d) to assess the acceptability , social validity, and treatment integrity of past interventions in preparation for future interventions. Relative to part (b), it is important to note that most interventions, when focused on the referred student, ultimately will focus not only on the alleviation of deficit or maladaptive behaviors, but also on the development, reinforcement, and maintenance of proactive replacement behaviors. Indeed, many students exhibit skill-deficit problems to the degree that even when their inappropriate behaviors decrease or cease, they still do not know how to enact the appropriate behavior. Thus, the RQC process needs to look especially at needed replacement behaviors and the reasons they are not present in the student's repertoire at the time of referral.

By the end of the initial consultation interview, the consultant should begin to organize the information collected into one of three categories and be ready to generate hypotheses. These three categories

BEST COPY AVAILABLE

are (a) information that is relevant to the referred and operationalized problem and is known, (b) information relevant but unknown, and (c) information that is irrelevant. The first category involves information that is relevant to the referral situation as currently defined and understood by the consultant and consultees and that is known to exist and to be true. For example, if a fourth-grade teacher, who has referred a student with a reading comprehension problem, is asked the grade level where the student can identify a reading passage's main idea 100% of the time, and she responds that it is at the 3.2 reading level, then this information is relevant and known. From this information, a tentative hypothesis can be made that the student is unable to identify the main idea of passages at the 4.0 level because she has not yet learned the skills nor sufficiently experienced reading passages between the 3.2 and 4.0 levels to be successful.

The second category involves information that is relevant to the referral situation yet is unknown. Given the same example, suppose the classroom teacher does not know at which grade level a student can identify a reading passage's main idea 100% of the time. This information, then, is relevant but unknown, and it now becomes necessary to collect and analyze this information so that hypotheses related to this situation can be generated as needed.

The third category involves information that is irrelevant to the referral situation. For example, a new sibling at home may be used to explain why a student is suddenly having difficulty in reading, yet this information does not sufficiently explain why no student problems in math, spelling, and written expression are similarly observed. While it seems that the irrelevancy of certain information is in the eye of the beholder, the consultant can avoid some of this subjectivity by using research and the professional literature as a guide. In addition, the consultant can always collect data to determine the irrelevancy of any piece of information. At any rate, when information is determined to be irrelevant to a specific referral situation, it should simply be discarded or ignored. From a consultation perspective, however, this action should be explained to all consultees so that they understand the reasons why the information is irrelevant and so that this information will no longer be used to explain or understand the referred problem.

The Development of Hypotheses

After completing the needed consultation interviews and collecting the necessary relevant information, the RQC process proceeds to the development of hypotheses that explain the now-clarified and behaviorally operationalized referral concerns. At this point in the process, the school psychologist and others have a great deal of information about the referred behavior, the settings within which this behavior occurs, and other significant ecological environments and contexts related to the referred student and the referral situation. Now, it is time to integrate all of this information and generate hypotheses that answer the question, "Why is this referral situation happening?" These hypotheses may be generated from any professional perspective, use any theoretical (or other) orientation, and involve any number of settings, individuals, or conditions, *but* they must be relevant, predictive, and measurable.

Relative to format, hypotheses are organized into three components: (a) a restatement of the referral situation, (b) the word "because" to signify that a explanation of that referral situation is to follow, and (c) the explanation itself. Visually, this format looks like this:

"(The Referral Situation) occurs because
(Hypothesis as to why)."

An example of a good hypothesis would be: "Johnny hits Lisa during unsupervised lunch times (the Referral Situation) because Johnny's friends (Dave, Mike, and Alex) reinforce him for doing so (the Hypothesis)."

It is through the development of relevant, predictive, and testable hypotheses that school personnel move from merely accumulating, describing, and reporting the facts related to, for example, a referred student's academic or social status to functional explanations as to why referred problems occur. Eventually, these hypotheses will help to directly link the RQC assessment process with specific and strategic interventions such that a high probability of successful interventions can be implemented.

The hypothesis domains. From a psychoeducational perspective, a number of empirically-devised models have been developed to integrate the research literature and to explain specific student outcomes (Centra & Potter, 1980; McKee & Witt, 1990; Rosenfield, 1987). These models have been synthesized into a single, summary model where student outcomes have been operationalized as (a) academic skill outcomes, (b) cognitive/metacognitive skill outcomes, (c) social skill outcomes, and (d) adaptive behavior skill outcomes. These outcomes are directly and indirectly impacted by eight different conditions or domains that exist in most students' worlds: family, neighborhood, community conditions; school/school district conditions; within school/classroom conditions; teacher characteristics or conditions; teacher performance/teacher effectiveness conditions; curricular characteristics and conditions; student characteristics and conditions; and student academic/learning support behavior conditions. The information in each of these eight domains can be used to generate hypotheses that explain why one of the four students outcomes is a problem for a referred student. For example, a student may be academically underperforming *because* the student–teacher ratio in the class-

FIGURE 1. Domains of hypotheses generation.

Referral Question Consultation Problem Solving
(RQC)
Examples of Hypotheses Areas

I. Child Characteristics/Conditions

Cognitive Areas:

- Adequate short and long-term memory (auditory, visual)
- Length of attention span
- Self-monitoring skills
- Impulsivity (inability to delay long enough to think/behave)
- Inability to integrate visual/motor/auditory tasks
- Lacks prerequisite academic skills for task
- Other

Behavioral Areas:

- Self-control
- Attributions (beliefs — others out to get me, parents do not want me to do well in school, I expect to fail, if I do not fight first then I will be hurt, my parents want me to fight back, etc.)
- Social skills
- Other

Health Areas:

- Hearing, motor, vision skills
- Specific health condition related to referral problems
- Side effects of medication
- Speech/language difficulties
- Fatigue results in higher activity, less ability to focus, etc.
- Medication cycle not appropriate for school day/activities

Other

- Excessive absences
- Language other than English

II. Peer Characteristics/Conditions

- Peers reinforce inappropriate behavior
- Peers do not provide appropriate/adequate models
- Social/Academic skills of peers significantly higher (lower) than referred student
- Peers taunt/instigate student to engage in inappropriate behavior
- Expectations/values of peer group influence student

III. Curriculum Characteristics/Conditions

- Curriculum too easy or difficult
- Curriculum not relevant to child experiences/understanding
- Curriculum presented in a way that relates to child weaknesses (lecture/auditory, etc.)
- Curriculum presented too fast for student learning rate
- Insufficient opportunity to practice skills
- Length of curriculum assignments too long for attention/concentration skills of student
- Philosophy of curriculum presentation too narrow (e.g., phonics only)

IV. Teacher Characteristics/Conditions

- Teacher expectations too high for skills of student (e.g., reinforcers at end of week, student needs daily)
- Feedback to student not frequent enough
- Rate of reinforcement too low for student needs
- Student and teacher physically too far apart
- Insufficient rehearsal time, direct instruction time, teacher guided practice
- Teacher fatigue, tolerance results in higher negative, less frequent feedback
- Teacher unfamiliar with curricular methods necessary for child
- Level of supervision (frequency/rate) too low for student needs
- Teacher teaching style related to child weakness areas

BEST COPY AVAILABLE

V. **Classroom/School/District Characteristics/Conditions**

- Classroom seating arrangement fosters problems (too close to peers, too far from teacher, near window or distractions, etc.)
- Rules/expectations in class/building far exceed skills of student to be successful
- Too many areas in building that are not supervised adequately
- Inconsistent discipline programs/philosophies/differences between staff who interact with same student
- Temperature
- Schedule of the daily activities
- Bus ride (length, problems on bus carry over to school, etc.)

VI. **Family/Neighborhood/Community Characteristics/Conditions**

- Parent discipline inadequate/too severe/teaches child aggression
- Conflict/physical aggression between parents/guardians
- Lack of or low levels of supervision
- Different values/expectations between home/school
- Parent academic skills too low to help child
- Reading and related academic activities do not occur in the home
- Parent difficulties (substance abuse, etc.) result in inconsistent parenting, low levels of supervision, negativity
- Parent unable/unwilling to reinforce school-related academic/behavior strategies in the home
- Parent permits child to be around inappropriate adults/peers in community
- Parent expectations too high for child/too much pressure
- Parent unwilling/unable to meet health/nutrition/basic needs of child resulting in absences, inability of child to concentrate on tasks, tardiness, etc.

room is too high. Or, a student may be aggressively acting out *because* he is angry about and unable to cope with his parents' upcoming divorce.

To simplify the RQC process, the eight research-based domains have been reorganized into six areas (Figure 1) that are used to generate the hypotheses which drive the RQC process. These six areas have been described previously (Knoff & Batsche, 1991b, pps. 177–180) as follows:

1. Family, neighborhood, and community conditions. These involve characteristics or conditions of a referred student's family, neighborhood and community as they relate ultimately to effective teaching and student learning outcomes. They emphasize the importance of such factors as a healthy home environment, parenting style, levels of supervision and feedback, and their impact on a student's school readiness and success.

2. Within-classroom/school/district conditions. These involve favorable and/or unfavorable characteristics and conditions within a referred student's classroom and school building such as the physical plant, the pupil–teacher ratio, the presence of instructional resources (e.g., computers, audiovisual equipment), professional development opportunities for staff, the administrative and instructional organization of the building, and other conditions that explain teacher effectiveness. This area also extends to characteristics and conditions within the school district that impact classroom instruction and student achievement.

3. Teacher characteristics/performance/effectiveness conditions. These involve characteristics and conditions that teachers bring to the classroom that ultimately translate into effective instruction skills and behaviors that affect student learning (e.g., background characteristics, professional training). Also involved are those empirically identified skills, activities and conditions that teachers perform to make their instruction effective and impactful (e.g., use of curriculum, ability to adapt instruction).

4. Curricular characteristics/conditions. These involve characteristics and/or conditions of the curricula being used and include the curriculum's content as well as the processes used to ensure student learning and mastery.

5. Peer characteristics/conditions. These involve characteristics and/or interactions with a referred student's peer group that become either antecedent or consequent stimulus control conditions for specific behaviors. While these peer characteristics may be real or simply perceived by the referred student, they, nonetheless, do assert some level of control over a referred situation.

6. Student characteristics/conditions. These involve often pre-existing characteristics and conditions that relate primarily to a student's health/development, cognitive and academic ability, educational attitudes, and readiness for academic and social learning. These characteristics directly relate to those academic behaviors that support learning progress and achievement. These characteristics and conditions also involve those behaviors students exhibit that directly support their academic and social learning and progress such as self-competence skills, social skills, and the student's effective use of the teacher and teacher time.

A case study follows the complete description of the RQC process. This case study will provide examples in each of these six hypothesis areas. For now, it is important to note that hypotheses provide a possible explanation for a referred behavior or situation. This eventually sets the stage for the development of interventions. Hypotheses are developed by a variety of professionals representing different disciplines related to the behavior of concern. The hypothesis always follows the format, "The referral situation occurs *because* of a hypothesized reason."

The Development of Predictions

The next step in the RQC process is the development of predictions. Predictions are statements, developed from specific hypotheses, that identify what should or should not happen if a hypothesis is true or untrue, respectively. For example, if a hypothesis is "A child aggresses because his peers verbally taunt him," then prediction statements would be: "When peers verbally taunt the child, then the child will aggress to the peers," and "When peers do not verbally taunt the child, then the child will not aggress to the peers." Or, if it were hypothesized that "Mary is able to complete independent seat work in reading because her teacher makes sure that she masters the material during reading group time," then our prediction statements would be: "When Mary's teacher makes sure that Mary masters material during reading group time, then Mary is able to complete independent seat work in reading," and "When Mary's teacher does not make sure that Mary masters material during reading group time, then Mary is not able to complete independent seat work in reading."

It is important to note two things about these prediction statements. First, prediction statements are written in an "If ... then" or "When ... then" format. More specifically, prediction statements state that" "*When* ... (the hypothesized reason for the referral concern occurs), *then* ... (the referral concern will be exhibited or will not be exhibited).

Second, prediction statements set up a situation whereby the hypothesis *and its converse* are both evaluated. That is, it is necessary to demonstrate that the referral concern exists when the explanatory hypothesis is true, and it is also necessary to demonstrate that the concern *does not exist* in the absence of the hypothesized conditions. For example, given the situations just described, it is necessary to demonstrate that the child aggresses only when his peers verbally taunt him. If he aggresses when the peers ignore him, then the hypothesis is not true. Similarly, it must be demonstrated that Mary completes her independent seat work in reading only when her teacher makes sure that she has mastered the material during reading group time. If Mary does not complete her independent seat work even when her teacher makes sure that she has mastered the material during reading group, then the hypothesis is not true.

A final, important point about predictions is that they must be evaluated without changing the student's "natural" environment whenever possible. That is, predictions should be tested, as much as possible, without implementing new interventions and, thus, without changing the referral setting. If a student, for example, was referred because he was out of his seat a great deal of the time, and your hypothesis was that he gets out of his seat during unstructured times in the classroom, your prediction statements would say that "When unstructured time occurs in the classroom, then the student will get out of his seat," and "When structured time occurs in the classroom, then the student will stay in his seat." To evaluate these prediction statements in a naturally occurring way, a member of the group needs to observe the teacher during times when she or he routinely allows the classroom to be structured and unstructured, respectively. If the teacher were asked to plan special structured and unstructured times, for the purpose of observation, this would constitute an intervention that changes the normally occurring classroom routine. When such changes occur, in the absence of baseline data and a multiple baseline or reversal design, we can not truly be sure whether the referred student's behavior occurred due to the classroom's typical structure (or unstructure) or the change that we created in the classroom routine. To summarize, prediction statements functionally arrange specific hypotheses such that they can be confirmed or rejected. In addition, prediction statements are written in an "If ... then" or "When ... then" format. Finally, prediction statements are written such that the hypotheses can be evaluated in the student's "natural" environment whenever possible.

The Development of Referral Questions

Referral Questions are data-based questions, derived from specific prediction statements, that (when answered) will quantitatively confirm or reject hypotheses related to a referral concern. More specifically, Referral Questions are typically yes or no questions, or questions that relate to behavioral frequency, duration, latency, or intensity. Referral Questions are important for a number of reasons. First, Referral Questions actually drive the assessment and decision-making process. While assessment procedures must be reliable, valid, and psychometrically sound, the form and format of the Referral Questions actually determine which assessment methodologies must be used. Second, Referral Questions provide an internal check of the RQC process to ensure that a parent or teacher's referral concerns are still being addressed. Third, Referral Questions help to organize the report-writing process. In fact, reports documenting the confirmation of hypotheses, the development of interventions, and the successful results of those interventions can be structured in a question-and-answer format around the referral questions. Thus, reports should do more than describe the referred student; they should answer questions that lead to and relate to interventions.

1. They must be clearly defined, be directly related to the previous prediction statements, and require data that are observable and measurable.

2. They must be agreed upon by the referral source and other evaluation team members, and they must lead to or have the potential to lead to interventions, not labels.

3. They should result in clear, definitive answers. Referral Questions should be able to directly confirm or reject hypotheses generated to explain referred problems.

Writing Referral Questions. In general, Referral Questions are simply the prediction statements put into a question format. However, as prediction statements typically involve (a) a prediction statement and its converse, and each of these statements involves (b) a conditional statement (i.e., "if this condition occurs ...") and an outcome statement (i.e., " ... then this behavior will result"), then many times, two to four referral questions will be necessary to test a hypothesis. For example, if the prediction statements involve conditional and outcome statements that can be answered by yes/no questions, then two referral questions will be needed to address the original hypothesis. If the predictions involve two distinct conditions and two distinct outcomes, then four separate referral questions will be required. And, if the predictions involve a condition or outcome that can be answered by a yes/no question, with the remaining condition or outcome involving two distinct circumstances, then three separate referral questions will be required.

Using one of the earlier examples, the evaluation team predicted that "When peers verbally taunt the child, then the child will aggress to the peers," and "When peers do not verbally taunt the child, then the child will not aggress to the peers." Here, the referral question for the conditional part of the prediction should be: "Does the peer group verbally taunt the child?" The referral question for the outcome part of the prediction should be: "Does the referred child act aggressively with the peers?" Note how the two referral questions meet the characteristics of effective referral questions just stated. Note also that both the conditional and outcomes statements can be answered by a "yes or no" question, respectively. Thus, only two referral questions are needed for these prediction statements.

Using the second example, the team predicted that "When Mary's teacher makes sure that Mary masters material during reading group time, then Mary is able to complete independent seat work in reading," and "When Mary's teacher does not make sure that Mary masters material during reading group time, then Mary is not able to complete independent seat work in reading." Here, again, both the conditional and outcomes statements can be answered using "yes or no" questions, and thus, only two referral questions are needed. These referral questions should be: "Does Mary's teacher make sure that Mary masters material during reading group time?" and "Does Mary complete independent seat work in reading?"

Parenthetically, if prediction statements involving two distinct conditions and two distinct outcomes were desired, the predictions could be adapted to read: "When Mary's teacher spends 10 minutes or more of individual reading instruction per day with Mary, then Mary completes 90% or more of her independent seat work in reading," and "When Mary's teacher spends less than 10 minutes of individual reading instruction per day with Mary, then Mary completes less than 90% of her independent seat work in reading." In this situation, four separate referral questions will be required; "Did Mary's teacher spend 10 minutes or more of individual reading instruction today with Mary?" "Did Mary's teacher spend less than 10 minutes of individual reading instruction today with Mary?" "Did Mary complete 90% or more of her independent seat work in reading today?" and "Did Mary complete less than 90% of her independent seat work in reading today?"

Once Referral Questions are developed, assessment begins. This assessment can be done by anyone on the multidisciplinary team, but the school psychologist and the classroom teacher are typically the best candidates. Significantly, most RQC referral questions involve the direct assessment of the instructional process, academic work, or student/teacher/peer behavior *in the student's classroom,* the primary setting where the referred problem is occurring. These assessments involve low-inference procedures (e.g., the use of behavioral observation or curriculum-based assessment or measurement); they use multitrait, multimethod assessment procedures, and they directly link assessment and intervention. Assessment within the RQC process follows other best practices approaches (Shapiro & Lentz, 1985):

1. Assessment must reflect an evaluation of the behavior in the natural environment (i.e., the referral setting).

2. Assessment should be idiographic rather than nomothetic (that is, functionally related to the referred student, specifically).

3. What is taught (social or academic) should be what is tested.

4. Strong links must be present between the results of the assessment and the behavior targeted for intervention.

5. Assessment methods must be capable of providing ongoing evaluation of the intervention.

6. Methods chosen for use in assessment must be empirically validated and must reflect the multimethod, multitrait, multisetting criteria previously outlined.

7. Low-inference procedures should take preference over high-inference procedures.

Once data are collected, then the referral questions can be answered, and the original hypotheses can be confirmed or rejected. At this point, the multidisciplinary team can take the confirmed hypotheses, begin to develop intervention plans, and outline a formative report organized around the hypotheses tested, the referral questions generated, and the data collected.

Selecting and Implementing Interventions

As noted previously, referral questions are simply prediction statements placed into a question format. If the answers to the referral questions confirm the original hypothesis, then the intervention directions necessary are fairly obvious. For example, if the team confirms that the student is aggressive with peers only when (or most often when) the peer group verbally taunts him or her, then the intervention program should either (a) stop the peers from taunting the students (possibly through group dependent or independent procedures) and/or (b) teach the student to handle verbal taunts in a more appropriate manner (possibly through social skills training). If the team confirms that Mary completes her independent seat work in reading only when (or most often when) Mary's teacher makes sure that Mary masters material during reading group time, then the intervention program should (a) encourage and reinforce Mary's teacher for ensuring that Mary masters material during reading group time, (b) try to decrease the teacher-directed time that Mary needs toward reading mastery, and (c) increase Mary's self-monitoring and self-maintenance skills during independent seat work, once again, to facilitate the mastery process.

RQC Written Reports

For the typical referral, a great deal of work goes into problem solving, completing the RQC assessment process, and implementing interventions. To be completely meaningful, however, school psychologists and others must be able to effectively communicate the result and impact of these processes. While consultation with a teacher or parent often permits direct communication with the referral source, the written report is required to meet federal, state, and/or district requirements and to communicate with referral sources and significant others, when direct interaction is not possible. Reports can be quite lengthy when they are the only vehicle for communication. But, to be effective, they must communicate effectively.

When teachers receive a report, they look for information that relates, in a primary way, to the referral concern and intervention strategies. Thus, it is critical for school psychologists and others to organize a report in a way that makes it easy for teachers to find the information they need and to understand what they are reading. RQC reports typically use a "question and answer" format with the referral questions providing advanced organizers for each section of the report. Given this format, the assessment process is reported for each referral question, as are the specifics of what each team member did and which assessment procedures were used. Because RQC reports use Referral Questions that respond directly to teachers' concerns and avoid the use of psychological jargon, they often seem more "personalized" and "tailored" to the teachers' needs. That is, teachers see their own questions in print, thus increasing the relevance and their commitment to the contents of the report.

Ultimately, the RQC report discusses the data that answer the stated referral questions; the hypotheses that are confirmed and rejected; and interventions that are definitive, related to classroom behavior, and based on the completed process. Critically, the RQC report does not reveal out-of-context test scores that (a) referral sources often do not understand, and (b) usually require high levels of inference relative to the development of interventions. Thus, readers of the RQC report should have no difficulty understanding the data reported or its connection to the interventions suggested. Indeed, the entire RQC report is geared to the delivery of interventions and services, the ultimate goal of the RQC process.

The RQC report usually has three general sections: (a) Background Information; (b) Answers to Referral Questions, and (c) Intervention Plan. The *background information* section contains relevant and known information from the review of the student records and the various consultative interviews held throughout the RQC process. As with all referrals, a tremendous amount of information is available when a report is about to be written, and the school psychologist and others need to separate the relevant things that a teacher needs to know to implement successful interventions from the irrelevant. One rule of thumb in this regard is to include only information directly related to the referral questions asked or to the successful implementation of interventions. All other information should be considered confidential and/or unnecessary.

While the basic information in the *Answer to Referral Questions* section has been discussed previously, it is important to (a) use the actual referral questions from the consultative interview in the report; (b) include the name of the referral agent responsible for the development of each question; (c) include the assessment strategies and procedures used; and (d) answer the questions as briefly as possible, using information that employs the simplest language and that is directly focused on interventions.

The *intervention plan* section should be based on the actual answers to the Referral Questions. Typically, an intervention plan includes four components:

1. Assessment Outcomes: A brief summary of the assessment results so that a clear rationale for the intervention is provided.

2. Intervention Strategies: Very specific, "how-to-do-it" guidelines designed to improve the behaviors or problems relevant to the referral concern.

3. Expected Outcomes and Definitions of Success: Specifically, what will happen as a result of intervention, and what are the criteria (over time) that constitute "success"? In essence, this section answers the question, "Which behavior(s) or outcomes should the referral agent expect to see if the intervention is working?" and "How long must the intervention be in place before change is seen, and will the intervention need to be adapted as the referred student's behavior changes over time?"

4. Personnel Responsible: Specifically, who will be responsible for implementing the intervention? As this may involve a number of individuals, specific people (or positions) can be named along with the specific component(s) of the intervention that they will be responsible for.

To summarize, the purpose of the written report is to communicate essential information in a way that the referral source can use to implement interventions. In accomplishing this, the school psychologist should be able to (a) select appropriate information for the Background Section; (b) answer referral questions in a definitive manner by selecting only the information that is relevant and that contributes to the development of interventions; (c) identify the appropriate personnel necessary to implement the interventions; and (d) identify expected outcomes that are realistic, given the interventions recommended, and the timelines needed for full implementation in the classroom (or other) setting.

Case Study

To briefly review and reinforce the steps and utility of the RQC process in a functional way, a case study is presented. It must be noted that a fairly open-ended case vignette was chosen to demonstrate how hypotheses can be generated in each of the six areas discussed in the Development of Hypotheses section. In addition, the link between assessment and intervention, once again, is emphasized, as is the importance of pragmatically moving through Problem Identification and Operationalization; Replacement Behavior Identification; Hypothesis, Prediction, and Referral Question Generation; Assessment; and Intervention Plan Specification and Development.

Case vignette. Joe is in fourth grade. He gets out of school at 3:00 p.m. each day. During the past month, at around 2:30 p.m. Joe has begun to have behavior problems in the classroom, often ending up in the principal's office and missing the bus. These behaviors involve yelling at and pushing peers, not responding to teacher requests, and needing to be physically guided and accompanied down to the principal's office. He has been sent to the principal's office on eight occasions during the past 20 school days, and the teacher and the principal are upset both about the intensity of the behavior and the fact that it appears unprompted, unpredictable, and unresponsive to the interventions (i.e., sending him to the principal's office) thus far. Both of Joe's parents work, and thus, they have not yet been available for a home–school intervention program. In fact, Joe's mother has recently gone back to work part-time for the first time since Joe has been in school. Significantly, on a few occasions, the principal has had to drive Joe home after he missed the bus, leaving him with a neighbor until his parents come home from work. The principal has noted that Joe's neighborhood is not in one of the safest areas of town.

The teacher and principal decide to meet with the other fourth grade teachers to RQC this problem, hoping ultimately to develop an intervention plan that is more successful. Following are the hypotheses, predictions, and referral questions that they generated organized in the six hypotheses areas discussed earlier. Note that numerous hypotheses could be generated beyond those listed below and that, for some cases, hypotheses may not be generated or exist in all six hypothesis areas.

Hypothesis 1: Family/neighborhood/community condition. Joe acts out in class at 2:30 p.m. in order to avoid the bus because he does not want to go home to an empty house and be alone.

Prediction A: When Joe knows that his mother is not going to be home when he gets there, then he will act out at 2:30 p.m. in order to miss the bus.

Prediction B (Converse): When Joe knows that his mother *is* going to be home when he gets there, he will not act out at 2:30 p.m. and will take the bus home.

Referral Questions: Will Joe's mother be home when he gets home? (Yes/No?) Does he act out in class at 2:30 p.m.? (Yes/No?)

Assessment Approach: Observation; Parent or Student Self-Report.

Possible Interventions: Arrange for Joe's participation in an after-school program on days when his mother will not be home. Arrange for Joe to go to a friend's house on days when his mother will not be home. Help Joe to cope with his fear or anxiety about being home alone. Give him the 800-number after-school hotline number for latchkey kids.

Hypothesis 2: School/school district condition. Joe acts out in class at 2:3 p.m. in order to avoid the bus because he is being picked on and teased by some of the students on the bus.

Prediction A: When Joe gets picked on by students on the bus during the morning run, he will act out at 2:30 p.m. in order to miss the bus that afternoon.

Prediction B (Converse): When Joe does not get picked on by students on the bus during the morning run, then he will not act out at 2:30 p.m. in order to miss the bus that afternoon.

Referral Questions: Did Joe get picked on by students on the bus during the morning run? (Yes/No?) Does he act out in class at 2:30 p.m. (Yes/No?)

Assessment Approach: Observation; Student, Per, and/or Bus Driver Report.

Possible Interventions: Have the principal deal with the other students and their behavior. Role play with Joe ways to stop doing those behaviors that prompt the teasing and/or how to ignore it. Arrange for Joe to sit and interact with peers who are popular/accepted by the students doing the teasing. Help Joe to cope with his reactions to the teasing.

Hypothesis 3: Classroom condition. Joe acts out in class at 2:30 p.m. because this is an unsupervised time and his peers are teasing him such that he gets angry.

Prediction A: When there is little supervision and Joe's peers tease him, then he will act out at 2:30 p.m. and be sent to the principal's office.

Prediction B (Converse): when there is appropriate supervision and Joe's peers do not tease him, then he will not act out at 2:30 p.m. and not be sent to the principal's office.

Referral Questions: Is there appropriate supervision at 2:30 p.m.? (Yes/No?) Do Joe's peers tease him? (Yes/No?)

Assessment Approach: Observation; Student or Peer Report.

Possible Interventions: Have the teacher take better responsibility for the supervision of his or her classroom. Have the teacher deal with the other students and their behavior. Role play with Joe ways to stop doing those behaviors that prompt the teasing and/or how to ignore it. Role play more appropriate social interactions between Joe and those peers doing the teasing. Arrange for Joe to sit and interact with peers who are popular/accepted by the students doing the teasing. Help Joe to cope with his reactions to the teasing.

Hypothesis 4: Teacher condition. Joe acts out in class at 2:30 p.m. because the teacher is tired and begins to provide less positive reinforcement and more negative reinforcement for inappropriate student behavior than at other times during the day.

Prediction A: When Joe's teacher begins to provide less positive reinforcement and more negative reinforcement to Joe for inappropriate behavior at 2:30 pm., then he acts out and is sent to the principal's office.

Prediction B (Converse): When Joe's teacher provides the same amount of positive reinforcement and negative reinforcement to Joe for inappropriate behavior at 2:30 p.m. as during the rest of the day, then he does not act out and is not sent to the principal's office.

Referral Questions: How much positive to negative reinforcement does Joe's teacher provide him for inappropriate behavior during the day? Does the teacher's positive reinforcement decrease and negative reinforcement increase at 2:30 p.m.?

Assessment Approach: Observation; Student or Peer Report.

Possible Interventions: Help the teacher to maintain his or her level of positive and negative reinforcement throughout the entire day. Help Joe to cope with less positive reinforcement (e.g., via teaching him self-reinforcement) especially at 2:30 p.m.

Hypothesis 5: Curricular condition. Joe acts out in class at 2:30 p.m. because that is when his class does free reading, an activity that he does not like because of his low reading skills.

Prediction A: When Joe is expected to do free reading at 2:30 p.m. then he acts out and is sent to the principal's office.

Prediction B (Converse): When Joe is not expected to do free reading at 2:30 p.m. then he does not act out and is not sent to the principal's office.

Referral Questions: Is Joe expected to do free reading at 2:30 pm.? (Yes/No?) Does he act out in class at 2:30 p.m.? (Yes/No?)

Assessment Approach: Observation.

Possible Interventions: Arrange for Joe to do his free reading in books at his independent level of reading. Allow Joe to do his free reading with a peer willing to read to Joe. Allow Joe (and/or the class) to do a different activity that is less frustrating at 2:30 p.m. Use this 2:30 p.m. time for the teacher to work with Joe to increase his reading skills.

Hypothesis 6: Student condition. Joe acts out in class at 2:30 p.m. because he chose not to take his noontime dose of Ritalin.

Prediction A: When Joe does not take his noontime dose of Ritalin, then he acts out and is sent to the principal's office.

Prediction B (Converse): When Joe does take his noontime dose of Ritalin, then he does not act out and is not sent to the principal's office.

Referral Questions: Does Joe take his noontime dose of Ritalin? (Yes/No?) Does he act out in class at 2:30 p.m.? (Yes/No?)

Assessment Approach: Observation.

Possible Interventions: Make sure that the school nurse directly observes the administration of Joe's Ritalin. Provide Joe with an incentive to take the Ritalin every day. Consult Joe's doctor as to alternatives to address his need for noontime medication. Work with Joe's parents for a home–school collaborative intervention.

SUMMARY

While the sample case study may appear to be somewhat simplistic in its description, it clearly is able to generate a number of feasible, highly significant hypotheses. It is critical to note that each of these hypotheses, once confirmed, leads to different intervention recommendations and approaches. This reinforces the importance of using the scientific process that forms the foundation of the RQC process. Clearly, if there are so many potential intervention directions for a "simplistic" referral situation, then the clinician must introduce some level of empirical decision-making to the process such that the highest probability of successful intervention ultimately is implemented. To randomly attempt interventions is a disservice to both the teacher or parent involved and to the related student. And significantly, too many mismanaged intervention attempts will decrease the probability that teachers will continue to use the psychologist as a consultant, thus also decreasing the potential that future students will receive early and preventive services.

It also is critical to note that many referrals have large amounts of relevant and known information and that some of this information actually can be contradictory. Many clinicians attempt to integrate and reconcile every piece of information collected for a referred student, when this simply cannot be done. The RQC process recognizes that multiple hypotheses can be confirmed to help explain a referred situation but that, pragmatically, only so many interventions can be implemented at one time. Further, many times it is the *absence* of change that most burdens a referral situation, and the emergence of any change due to a planned intervention begins a process of even greater change. Thus, the one or two interventions that facilitate change are essential to many referral questions. The RQC process identifies these pivotal intervention directions in a way that is effective, efficient, and impactful.

School and other psychologists spend a great deal of their time in assessment and intervention activities yet, too often, they spend precious little time analyzing the impact and effectiveness of the problem-solving and decision-making approaches that they are using. Very little empirical work has been done, especially in school psychology, to compare and contrast different problem-solving and clinical judgment approaches and/or to investigate those variables that impact these processes primarily because few researchers have reviewed the various models and their attributes. The RQC process comes closest to an etiological model that uses behavioral decision theory approaches. A problem-solving model that parallels the scientific method, the RQC process, nonetheless, is antithetical to the approaches used today by many school psychologists. Thus, while RQC research to support a change in current field-based, clinical approaches clearly is important, the underlying foundation of the process has been shown to be valid for centuries. A paradigm-shift will be essential in order for the RQC process to be fully accepted in the field. The RQC process has a great potential to increase the clinical efficiency and effectiveness of field-based practices and, once again, to prove school psychologists' worth to their consumers. It is hoped that this article will help you, the reader, to revisit the origins and mechanisms of your decision-making processes and will initiate the paradigm shift needed to return school psychology practices to their empirical and scientific roots.

ANNOTATED BIBLIOGRAPHY

Knoff, H. M., & Batsche, G. M. (1991b). *The referral question consultation process: Addressing system, school, and classroom academic and behavioral problems*. Tampa, FL: Author.
This workbook is a step-by-step training manual designed to present the conceptual and functional components of the RQC method and to provide practice exercises, with feedback, for the reader. The RQC method is a seven-step procedure beginning with problem identification and proceeding through hypothesis development, assessment to address hypotheses, and interventions linked to verified hypotheses. Assessment is used both to verify hypotheses and evaluate interventions. It is, in essence, a programmed learning text that provides the reader with the opportunity to acquire new skills in linking assessment to intervention.

Elliott, S. N., Witt, J. C., & Kratochwill, T. R. (1991). Selecting, implementing, and evaluating classroom interventions. In G. Stoner, M. R. Shinn, & H. M. Walker (Eds.), *Interventions for achievement and behavior problems* (pp. 99–138). Silver Spring, MD: National Association of School Psychologists.
This chapter provides an overview of the problem-solving process involved in intervention selection and evaluation. In addition, a review of treatment acceptability, teacher empowerment, and treatment integrity that are critical to the effective use of classrom interventions is provided. Intervention evaluation is discussed in the context of intervention efficacy.

Kazdin, A. E. (1994). *Behavior modification in applied settings*. Pacific Grove, CA: Brooks/Cole.
Chapter three of this book provides an excellent review of methods to link behavior problems with assessment and intervention through a functional analysis of behavior. The functional analysis of behavior model is one method of develoing hypotheses about academic and social behavior that can be used in conjunction with the RQC method. This chapter reviews assessment methods that can be used both to validate the functional analyses as well as to evaluate intervention effectiveness.

Best Practices in Curriculum-Based Assessment

Edward E. Gickling
Pennsylvania Instructional Support Project

Sylvia Rosenfield
University of Maryland — College Park

Although it may seem unusual to compare fishing with curriculum-based assessment, the two do have a lot in common. To be successful in either endeavor, a person must be clear about the purpose of the activity, use the right equipment, and make a good presentation. For example, a well stocked fish and game store always carries a large variety of fishing tackle. Selecting the correct tackle depends upon where the person plans on fishing and what kind of fish are to be caught. Unless these purposes are clear, one can end up using the wrong equipment and bait, fishing in the wrong spot, and not catching any fish. The same is true for assessment. When the purpose of assessment is clearly defined, the equipment can be carefully chosen to meet the purpose, the process is carried out well, and the results are maximally useful. After individuals learn how to use the equipment and get the basics down, they have plenty of opportunities for challenge as novel situations present themselves and as the person tries to perfect various techniques. This analogy between fishing and assessment provides a useful metaphor for introducing curriculum-based assessment (CBA).

OVERVIEW

While there are different approaches subsumed under the general rubric of CBA (see Shinn, Rosenfield, & Knutson, 1989, for a discussion of these approaches), this chapter focuses on the approach originally developed by Gickling and Havertape (1981) and elaborated by Rosenfield and Kuralt (1990). In this chapter, however, two new issues are addressed: CBA's congruence with cognitively based instructional practices and its use as a peer-mediated learning strategy. Although clearly not limited to the practice of school psychologists, CBA provides useful and relevant instructional assessment information to psychologists working in the schools.

Instructional Assessment

CBA is a technique within the domain of educational assessment, which itself serves multiple purposes such as referral, screening, classification, instructional planning, and student progress monitoring (Salvia & Ysseldyke, 1985). However, assessment's most fundamental purpose is to design and deliver optimal instruction for all children (Johnston, 1987). In other words, instructional assessment's primary focus should be on providing relevant data to guide and manage student learning and to ensure that students are responding optimally to what and how they are being taught (Walker, 1992). Recognition of this essential purpose has evolved over the past decade, and CBA methods have played a major role as a technique for reaching the goal of this evaluation purpose.

Also related to the increased emphasis on instructional assessment has been a dramatic shift from an overreliance (and sometimes inappropriate reliance) on standardized/norm-referenced testing practices to more naturalistic and dynamic forms of student assessment. At its best, instructional assessment chronicles performance and development and sends a message that learning is not static but ever changing and evolving (Valencia, 1990). Therefore, assessment for instructional decision making requires a dynamic ongoing process rather than a yearly event, such as norm-referenced achievement testing. Unfortunately, instructional assessment can be misused when it is applied too narrowly, such as viewing it simply as another technique to obtain a set of scores as part of an assessment battery during a psychoeducational evaluation, rather than as a process which requires obtaining continuous snapshots of what students know and are able to do in response to what they are being taught. In this respect, CBA is very compatible with portfolio assessment, learning progress maps, student progress interviews, running records, and the like. Naturally, what goes into these snapshots must both be representative and directly and accurately reflect the student's actual work in the classroom.

Defining CBA

Descriptive terms such as "naturalistic" and "dynamic" reinforce the conclusion that the best possible instructional assessment practices occur as teachers observe and interact with students engaged in real tasks for real purposes (Valencia & Pearson, 1987). CBA, based on the same viewpoint, is defined as "a system for determining the instructional needs of a student based upon the student's on-going performance within existing course content in order to deliver instruction as effectively and efficiently as possible" (Gickling, Shane, & Croskery, 1989, pp. 344–345). It assumes that the most natural medium to use for instructional assessment is the day-to-day curriculum being taught in the classroom. The naturalness of the curriculum as the medium of assessment, along with a recognition of the importance of aligning assessment practices with instructional practices to favorably affect both learning and teaching, are the primary reasons for the development of curriculum-based assessment.

Basic Principles of CBA

Beyond meeting the basic requirements of being naturalistic and dynamic, CBA also meets requirements consistent with effective instruction, reading development, and learning theory. While the intent of the naturalistic assessment movement has been to bring assessment back into the classroom and to return the curriculum to a more central role within the assessment and instructional process, such changes cannot occur independent of effective instruction, meaningful content, and the active and interactive nature of learning and teaching. This view has resulted in a number of fundamental changes with regard to how assessment should impact instruction and how instruction should be delivered to improve the academic abilities of all students. These changes, which represent a departure from many of the traditional tenets of testing and teaching, are reflected in the following principles:

CBA complements prevailing curriculum approaches. CBA was designed for use with a variety of theoretical approaches to teaching reading, mathematics, and other content areas. It adheres to a generic set of principles applicable to any number of curriculum programs and practices. In this sense, the CBA process is content free or neutral, because it is not dependent upon the use of any specific materials, methodologies, practices, or theoretical orientations.

CBA has, however, been positively influenced by the rationale and philosophical bases of problem solving, strategic learning and teaching, and certain aspects of whole language instruction. CBA, as an assessment procedure, is congruent with emphases upon providing students with opportunities to reach mastery by integrating assessment and instruction within and across content areas, keeping learning connected and coherent rather than fragmented, capitalizing on the use of good literature, working within meaningful contexts, and developing strategic learners. In this vein, CBA can be used by teachers to create the types of conditions that enable students to interact with original texts and gain meaning that yet avoid the flawed practice of teaching isolated skills and hoping that the pieces will somehow magically connect to develop mature strategic learners. CBA can also be used to help students acquire essential word recognition, word study, and fluent reading skills using the context of meaningful texts as much as possible.

CBA aligns assessment practices with what is actually taught in the classroom. With the curriculum as the context for assessment, teachers are better able to assess both the performance of their students and the effectiveness of their teaching practices. Moreover, CBA places as much emphasis on assessing how students are thinking about and processing their work as it does on assessing what they produce.

CBA starts with what the student knows in building an integrated program. Assessment and teaching practices traditionally have focused on a student's deficiencies without due regard for what the student knows and can do. This practice has caused practitioners to become predisposed to identifying student deficiencies at the expense of determining and building on prior knowledge, yet this knowledge is essential if the student is to maintain an active role in learning (Bloom, 1976). Ignoring the entry-level skills of students frequently results in fragmented learning when students are asked to work assignments which contain excessive amounts of unknown information. As a result, academic learning time is diminished. CBA is structured to help teachers plan instruction based on the entry-level skills of students, thus maximizing on-task time during learning activities. Again this approach matches current definitions of good instructional design in reading, mathematics, and other academic disciplines, by acknowledging prior knowledge as an important prerequisite to learning (see, e.g., Ysseldyke & Christenson, 1993).

CBA addresses the need to regulate task variability, task demand, and the pace of instruction to ensure student success. A mismatch often occurs between the limited entry skills of at-risk students and the ever changing demands of their school work. Correcting this type of mismatch necessitates both curriculum and instructional changes to create an appropriate fit or instructional match for the student. This correction permits the practitioner to keep task variability and task demand within appropriate levels of challenge, while regulating the pace of instruction to match each student's learning rate. If this match is not continuously monitored as part of the instructional process, the "gap" is likely to widen between the entry skills of those students academically at risk and their ability to master each new learning task.

The *instructional match* is a widely acknowledged and fundamental concept of student learning. It reflects the types of optimum learning and teaching conditions under which both students and teachers thrive. Optimal conditions occur when the learner is provided with an appropriate level of challenge and a realistic opportunity for success on a frequent and continuous basis. The combination of these two factors provide students with the perception that they have the knowledge and skill to be successful and therefore the motivation to master the task (Borkowski, 1990; Meichenbaum & Biemiller, 1990). This combination of challenge and competence can be viewed as a comfort zone, or the level where the student can accomplish the task comfortably. These comfort zones have been extrapolated from the reading and teacher-effectiveness literature (see, for example, Archer et al., 1987; Betts, 1946) to reflect instructional levels for reading and practice-related activities. As such, these levels reflect the conditions where students are able to work comfortably without being excessively challenged or frustrated by each learning task. The use of these ratios is fundamental when applying CBA; they serve as guidelines for assessing what students know and are able to do and for problem solving in regulating task difficulty. As guidelines, they represent entry levels for instruction and not exit-level values representing mastery. The ratios for instructional levels for reading- and practice-related activities are:

Reading	**Practice**
93–97% Known Information	70–85% Known Information
3–7% Unknown Information	15–30% Unknown Information

This ratio system reinforces the importance of looking for and building upon what each student knows. Planning instruction so that the level of challenge does not exceed these guidelines and therefore so that a high level of known information exists within each learning task makes it possible for each student to maintain a more active role in his or her learning. By building upon what a student knows and can do and by providing a student with an appropriate rather than excessive level of challenge, teachers can control for task variability while assuring the student of frequent and continuous success. By adhering to this process, teachers can take into account the natural variations in students' learning while still provide each individual with a high degree of task success.

CBA strives for high uniform scores among students. Traditional teaching practices have involved teaching students of differing abilities at the same pace using the same assignments, with the expectation that normal variations in students' scores will occur. Many schools continue to function under the premise that a single level of instruction is adequate and that those students unable to conform to this routine pace are somehow defective learners. Education has reinforced these perceptions through elaborate systems of screening, identification, labeling, and placement. The adverse effects of this process prompted Bloom (1976) to advocate for mastery learning. He recognized that the system of teaching was responsible for most defects in student learning rather than the students themselves. With mastery learning, and now with outcome-based and performance-based education, a student's progress is not compared against the calendar year; the pace of instruction is contingent upon the student's learning needs and the ability to master identifiable skills. Achieving mastery is contingent upon each student receiving and maintaining high uniform scores.

This approach does not deny that there will always be individual differences in student performance but rather assumes that the job of education is to reach students where they are and to teach them effectively and efficiently, not sort them along a normal distribution: "The normal curve is a statistical construct at odds with the purpose of education, which is to change a typical distribution of performance into a skewed curve of competence" (Wiggins, 1992, p. xi). To maintain high success rates for each student, educators must respect the differences among students by providing them with appropriate levels of challenge. This allows all students to earn high scores and enjoy the benefits which come from appropriately matched instruction.

CBA allows for the direct and continuous assessment of student progress. Concerns for accountability and for the assessment of ongoing performance are important to the CBA process. The dynamic features of instructional assessment permit users of CBA to constantly monitor how well students are processing instruction and progressing toward various outcomes, thus enabling detection of subtle changes in student learning. The analysis also permits evaluation of how successfully various classroom programs and support services are at maintaining students at instructional levels. Obtaining continuous snapshots of how the student is progressing and how instruction matches each student's learning needs is vital. Collections of work samples placed in portfolios, learning progress maps, and other relevant data are strongly encouraged. These and similar approaches facilitate the monitoring of student performance with respect to instructional goals.

The application of these basic principles in combination with current thinking in whole language and problem solving provides a coherent approach to instructional assessment and integrates assessment within the instructional design framework. Because control is maintained between curriculum difficulty and student entry-level skills, all students, including those at risk, can learn in a more optimal, less frustrating instructional environment. Thus, the CBA procedures contribute to effective instructional outcomes by determining where instruction should begin — based upon what each student knows and is able to do — and using this information to control for the excessive curriculum and instructional variance which fragment and frustrate learning for many students.

BASIC CONSIDERATIONS

Much concern exists today over the quality of classroom assessment in general and the classroom teacher's own assessments in particular. Stiggins and Conklin (1992) for example, noted that "teachers view instruction and assessment as separate activities. Integration of the two is done haphazardly and rarely to full advantage" (p. 148). They concluded that "most teachers either do not take the time or do not know how to make good use of assessment in presenting instruction, in evaluating it, and in making it more effective and meaningful" (p. 148). Regrettably, inadequate assessments lead to poor decision making in the classroom because the first stage of the problem-solving process is problem identification. The lack of identification leads to "inefficient instruction, and at worst . . . failure to learn and an attendant loss of student motivation to participate in the learning process" (p. 196).

Concern over the lack of adequate classroom assessment practices, coupled with the continuing concern over the inadequacies of traditional norm-referenced assessment in facilitating instructional outcomes for students (Reschly, Kicklighter, & McKee, 1988) has prompted school psychologists to integrate the concepts and procedures of different curriculum-based-assessment models into school psychology training and practice (Shapiro & Elliott, 1993; Shinn et al., 1989). This has led to increased acceptance of curriculum-based-assessment procedures by school psychologists. In a recent survey of school psychologists, Shapiro and Eckert (1993) documented that more than half of their sample agreed that the use of CBA in their practice results in less culturally biased assessments of students, is more accepted by teachers when assessing students with academic problems, and is more useful to parents and students than norm-referenced statements. Given that the formal history of CBA is less than 20 years old (Coulter, 1988), its current level of acceptance is encouraging.

Shapiro and Eckert (1993) noted, however, that the use of CBA is inconsistent and that there are insufficient training opportunities for school psychologists to develop real skills in applying CBA. While its literature base has been expanding, preservice and inservice training have lagged behind. Most training opportunities still resemble pull-out workshops rather than providing trainees with guided practice and feedback in real classroom settings and situations. Because of these training limitations, many school psychologists remain hesitant about fully participating in this new instructional assessment domain. Although they express considerable concern over the quality of classroom assessment, they remain uncomfortable embracing this new and changing role. They continue to wonder and raise questions about how best to be involved in working directly with the teacher within the classroom in conducting instructional assessment.

While classroom consultation and prereferral intervention are increasingly important facets of contemporary practice and an integral aspect of school service delivery options (Rosenfield, 1987), it should be stressed that reading about CBA, and other such practices, is only a beginning step. Receiving opportunities for guided practices as part of the instructional consultation process is crucial to feel comfortable and achieve mastery.

BEST PRACTICES

While it is important for practitioners to understand the theoretical basis of CBA and the need to align assessment practices with what is actually taught within the curriculum of the classroom, these concepts alone are insufficient to explain how the curriculum-based-assessment process is performed. The purpose of this section is to guide practitioners through the process and to provide them with a framework, using the assessment of reading as an example of the process. (For an example of how CBA can be used in mathematics, see Gickling et al., 1989).

Key Questions

Certain questions, which always need to be addressed when planning and guiding instruction, form the core of the curriculum-based-assessment strategy:

1. What does the student need to do in order to be successful within the curriculum? What does the teacher want the student to understand, develop, or demonstrate in relation to the curriculum being

taught? Specifically, which concepts, skills, strategies, procedures, or knowledge does the teacher want the student to acquire? The CBA process normally begins with clear expectations of the required curriculum goals of the classroom teacher. This process engages the teacher in selecting the appropriate outcomes for the student.

2. Which discrepancies, if any, exist between the anticipated outcomes established by the teacher and the performance of the student? An assessment of the student's performance within the actual classroom curriculum is used to determine whether an instructional match exists or not.

3. If an instructional mismatch exists, what prior knowledge and entry skills does the student need to develop to be successful? The assessment process proceeds to delineate what the student knows and is able to do in comparison to the specific skills, strategies, concepts, and knowledge which need to be acquired.

4. Are steps taken to match each learning activity or experience to the student's entry skills and learning needs as instruction progresses? The level of known to challenging information for each learning task is monitored using instructional ratios as a guide to sustain an instructional match. Fine-tuning of task difficulty is used throughout the instructional process.

5. Is instruction presented so that the student is learning as efficiently as possible? Is student learning managed so that both teacher and peer assistance is provided in a timely manner? Is there maximum use made of instructional time?

6. Is student progress regularly assessed, monitored, graphed, and used for instructional decision making? Is performance monitored to ensure that the student is actively engaged in the learning process?

Conducting Curriculum-Based Assessment

Unlike normative assessment practices which push students to the point of frustration during assessment sessions, the CBA process helps students to function comfortably. Conscientious efforts are made to activate the student's prior knowledge without creating frustrating experiences. The ratio concepts are used repeatedly to guide this process, and the evaluator is encouraged to look for what is known in the curriculum activity and to gradually incorporate or "fold in" what is unknown. Given the finite amount of time available for purposes of initial assessment, these rules have proven helpful:

1. Always look for what is known.
2. Never look for just the unknown.
3. Always build in success during assessment.

Although reading is used here to illustrate the CBA process, the four generic steps within the CBA process can be applied to any type of curriculum content. These steps are selecting, assessing, matching, and teaching. For example, after a teacher selects the objective and reading activity, the CBA process enables the practitioner to match the demands of the learning task with the student's entry skills on the basis of the assessment and to implement the instructional intervention. This 4-step process for reading involves the following activities.

Select a "workable passage." The concept of a *workable passage* is not to be confused with the concept of an *instructional level passage*. A passage well beyond the ability of a student to read comfortably can still provide valuable information from which to work — thus one use of the term "workable passage." The process begins with trying to gain some sense of the student's entry-level skills and to use that information to begin constructing reading activities on the student's instructional level. Most often the process begins with selecting a passage from the material which the teacher is using or has previously used with the student during reading instruction. In the early grades, this generally involves selecting a passage from a story in a basal reader, literature based text, anthology, and/or trade book. A few minutes may be spent discussing the story with the student to gain some sense of the student's prior knowledge and give the evaluator an indication of the student's oral skills.

To gain a measure of the student's ability to process print, a word search can be conducted by selectively pointing to words which the student has a high probability of knowing. Every fourth or fifth word, a more difficult word can be selected. The key to using this technique is to be selective and to maintain a lively pace. By keeping a lively pace, the word search should take no more than 2 or 3 minutes while covering 20 to 30 words. The process of searching for known, hesitant, and unknown words using this folding-in of difficult with easy words provides a measure of the student's working sight vocabulary without frustrating the student. If five or fewer errors occur, the student is asked to read the passage, since language and sight vocabulary should not be a hindrance to comprehension. If a greater number of errors is made, an easier passage may be selected. Another option is to modify the existing passage, making it easier for the student by taking into account the known, unknown, and hesitant words, and begin teaching at that point.

Assess contextual reading. The primary rationale behind having the student read the selection is to sample how the student interacts with the text. In an unobtrusive manner, the student's errors are marked. If there are any mis-called words or word delays, the student is provided with the correct response within

3 seconds so as not to disrupt comprehension. At the conclusion of passage reading, a dialogue with the student is conducted by asking unaided or general types of questions, such as "Tell me what the story was about." and "Can you tell me more?" If the student has difficulty, aided questions are used to help guide the student's ability to respond (Paratore & Indrisano, 1987). This process is similar to that used in informal reading inventories and some reading tests. However, the unique characteristic here is that the material used for the assessment is from the student's own classroom curriculum materials.

A second reason for asking the student to read the selection is to obtain a measure of reading fluency. This is done by taking one-minute time samples as the student reads. Fluency samples are used both for planning and for motivating students. They can be taken before and after reading practice and to measure progress at frequent intervals throughout the calendar year. They can also be used as measures of oral and silent reading depending upon the reading skills of the student and the purpose of the assessment. The time-sampling procedures developed in the curriculum-based-measurement literature can be used for this purpose (see, e.g., Deno & Fuchs, 1987).

Match reading instruction. The matching process involves three concurrent uses of decisions, each of which is essential to the design of good instruction. First, using the data from the word search and from the contextual reading sample, the teacher makes an initial decision concerning the types of reading support which should be provided. The reading framework helps to answer questions about whether or what kinds of mechanical and/or comprehension needs should be addressed. Specific questions concerning the language concepts and sight vocabulary, word-study skills, the recalling and retelling of information, oral and silent reading fluency, and the metacognitive processes used by the student are examined. Concerns for the interaction of these dimensions helps maintain a holistic picture of the reading process and of what is required to develop a more mature reader.

The second type of decision involves designing opportunities for the student to work at his or her instructional level. By assessing what the student knows, the teacher can select curriculum material that provides an appropriate level of challenge or can regulate the level of challenge by modifying existing materials so that they are matched to the student's entry-level skills. The most important point is to capitalize on the student's prior knowledge in order to maintain a comfort level (high success rate) during instruction.

The third set of decisions involves selecting appropriate strategies to develop the student's reading skills which have been targeted for instruction. Such strategies need to be used in a holistic framework to avoid the pitfalls of skill fragmentation. This can be accomplished efficiently by looking for both what the student knows and what the reading task requires. Based upon relevant instructional data, teaching strategies can focus on what is known and what is needed. The instructional integrity of the text is never sacrificed because the skills which need developing are taken directly from the text, taught and practiced, and folded back into the original text as part of the instructional design.

Teach the student. Knowing the student's skill level and ways to regulate the level of challenge within the material, the teacher can begin the teaching process. During the teaching session, appropriate instructional strategies are used with teaching moving at a pace which takes into account the student's learning rate (for example, the number of repetitions necessary to develop mastery, which varies among students). Feedback is provided continuously, progress is monitored and recorded, and the learner is positioned to achieve success.

Acquisition Rate, Retention Rate, and Degree of Need

Even though CBA's major role is in the instructional design process, it can also be used to provide relevant information about the learner's rate of acquisition and retention of new material as well as to help determine if any other resources are needed to help the student be successful. It is common knowledge that students learn differently, that they acquire knowledge and skill at different speeds, and that they require different amounts of repetition and practice to master various skills. The relative ease with which new information and skill is acquired is referred to as *acquisition rate.* A student's ability to retain and use information or skills in meaningful ways is referred to as retention rate. These two features constitute what is referred to as *student learning rate.*

A common misconception among educators is that if students are not keeping pace and learning at the same rate as other students, they have a slow rate of learning. Without CBA data, however, it is often unclear whether the student is failing to learn because of student-centered problems or because instruction is provided at an inappropriate level of difficulty. Until it can be determined that the student is working on an instructional level and can actively use his or her prior knowledge to an advantage in the instructional setting, it is difficult to gauge the student learning rate. This is one reason why the CBA process is so valuable early in the referral process. By regulating the level of challenge and maintaining the student at an optimal instructional level, educators can systematically determine the student's rate of learning on new curriculum tasks. Having created optimal learning conditions, the teacher is in a position to determine both the amount of support required to sustain the level of student's success within the regular classroom and the support (degree of need) necessary beyond what the classroom teacher can provide. In such cases, other resources within a continuum of services need to be explored.

Fostering Assessment Partnerships

In consulting with classroom teachers, the authors have come upon two frequently asked questions: "How can I do this with one child when there are 30 in my classroom?" and "Why single out one child when there are others just like him?" These two questions arise because teachers have responsibility for teaching 25 to 30 children and their focus is on group instruction. Consultants who apply techniques which enable teachers to change instructional assessment from a labor intensive one-on-one process to one which makes use of small-group learning and self-assessment increase the likely acceptability and implementation of critical instructional techniques. This transfer can be accomplished more easily if the questions are reframed to: "How can the focus be shifted to be more student centered and less teacher centered?" and "How can we get students to take a more active role in guiding their own learning through participation in a self-assessment process?"

Within the Pennsylvania Instructional Support Team (IST) project, with which one of the authors is associated, groups of teachers have collaborated to develop classroom routines to transfer much of the assessment process directly to their students. Keeping the instructional framework in mind, they selected grouping arrangements to facilitate the content and strategies they wanted their students to learn and apply. Their efforts concentrated on developing an instructional management system that supported active student involvement at each stage of learning. By integrating CBA with the principles of whole language and cooperative learning, they have provided for the continuous assessment of all their students, made certain that their students have been taught effectively and efficiently within their language arts curriculum, and have been accountable for the individual progress of each student. The motivating factors behind these changes included the desire (a) to use CBA in group classroom practices, (b) to capitalize on the support of an IST consultant, and (c) to eliminate student frustration and instructional fragmentation.

What follows is an abbreviated outline of how one creative set of teachers designed and implemented this group CBA process to fit their classroom routines, utilizing the four steps introduced earlier in this chapter.

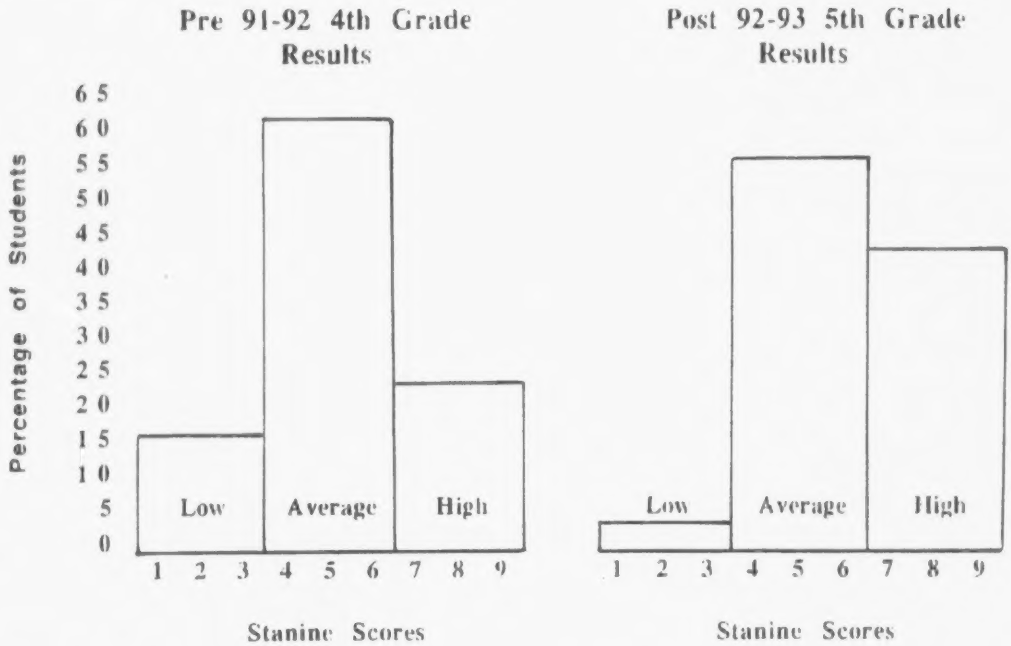
Select. The teachers begin by selecting and then introducing a story during whole or small group instruction. They discuss the title and illustrations, and assess for prior knowledge. Teachers then assign readings — paragraphs or page(s). They provide cards and markers for students to conduct personal "word searches" for unknown words and word concepts.

Assess. Students silently skim their assigned readings, writing unknown words on cards as they identify them (approximately 2 minutes). In cooperative learning settings, group members assist each other in identifying and defining each unknown word. Teachers time each individual student's oral reading for one minute, provide unknown words after a 3-second delay, note how each student interacts with the reading passage, and record student's reading errors. Upon completion of the assigned reading, the teacher dialogues with the individual student to determine passage comprehension by first asking unaided questions followed by aided questions when necessary. Teachers record comprehension, note any reading strategies used by the student, and record fluency and accuracy rates including the number of words read correctly per minute (wpm) and the types of reading errors on a CBA Record Form. Fluency and error rates are charted on a Student Profile Form.

Match. Next the teachers address the three sets of decisions essential to the design of good instruction. First, they use the information acquired to determine the types of reading goals they need to set for the students. Secondly, they design opportunities for the students to work at their instructional levels. Finally, they select the appropriate strategies. For example, they identify and match appropriate word recognition, fluency, and comprehension strategies to be taught and used in cooperative groups. Students are paired with a partner to learn unknown words and word definitions. They are taught to fold-in or "sandwich" both known and unknown words, keeping a ratio of 70% to 80% known material. A sequence of known (K) to Unknown (U) words might be, for example, K-K-K-U-K-K-U-K-K-U. The new vocabulary is folded back into the actual reading passage where it is combined with strategies for developing fluency. Three to five minutes of this type of practice is provided each day. Comprehension is also taught in cooperative learning groups using, for example, "Think Aloud" and "Retelling" strategies. Writing activities are also integrated into the planning and practice process.

Teach. The final step is to implement in the classroom the instructional design they have developed. The students themselves are taught how to implement specific reading strategies, work with meaningful content in context, integrate reading and writing instruction, work at other students' instructional levels, and monitor and record reading and writing progress. The importance of ensuring the success of other students is also considered within the group teaching process.

FIGURE 1. Reading Comprehension Scores.



Evaluation of CBA Partnerships

Although it is premature to discuss in depth the results of this type of group CBA effort, the preliminary data are extremely encouraging. Results from a pilot school in northeastern Pennsylvania, for example, show a dramatic shift in both teacher acceptance and student performance as measured by reading comprehension. The data were collected toward the end of the fourth grade and again toward the end of the fifth grade on the same student population. There were 107 students in the initial sample at the beginning of the program, with 97 students remaining at the end of the study. Different grade level forms of the reading comprehension subtest of the Stanford Achievement Test were used as performance measures at the end of both grades. Figure 1 shows the comparative group changes, with the main intervening variable being the CBA small-group self-assessment and instructional intervention process.

SUMMARY

CBA represents best practice because it provides school psychologists, teachers, and other educational personnel with a method to assess student's academic needs and to link the information directly to instructional interventions. Unlike traditional assessment practices that test students on material disconnected from the context of the classroom, CBA uses actual classroom curriculum goals and materials to gauge student performance and to facilitate successful instruction. It is based on the following set of principles:

- Although CBA is content free and can be used in any subject matter, it complements prevailing cognitively oriented curriculum and instructional approaches.
- The assessment process is performed using the natural context of the classroom curriculum, thus eliminating the need to translate assessment information back to the curriculum.
- CBA clarifies what the student knows and allows for the regulation of task variables, task demand, and the pace of instruction to ensure continued success in learning.
- CBA encourages the direct and continuous monitoring of student progress.

The CBA process includes four basic steps: the *selection* of goals and materials to help the student achieve success; the *assessment* of the student's entry skills as they relate directly to classroom materials; the decision-making process in which assessment information is used to *match* the student's entry level with appropriate instructional strategies; and finally, actual *instruction* — the outcomes of which are continually monitored to ensure that the instructional match is appropriate and that there is progress in learning the identified objectives.

Practicing school psychologists have shown increasing acceptance of CBA as part of their expanding role. For school psychologists involved in classroom-based consultation, the benefits of CBA continue to be apparent. It is hoped that the application of CBA peer- and self-assessment procedures and cooperative learning strategies, and their promising results, will make the assessment process even more attractive for use with school psychologists and classroom teachers in the future. If so, it will continue to be important to develop and provide access to skill training and guided practice in the application of CBA. Through the use of CBA procedures, school psychologists acquire an important set of skills for contributing to students' academic progress.

Best Practices in Performance Monitoring

Doug Marston
Minneapolis Public Schools

Gerald Tindal
University of Oregon

OVERVIEW

It was Saturday morning and my young son and I were looking at his baseball card collection when he asked, "Why are all of these numbers on the back of the cards?" Seeing a chance to explain the importance of baseball statistics I began to explain that numbers such as "batting average" and "runs batted in" showed how well a player had performed and helped his team win. But before my discourse ran too long he interrupted and said, "If these numbers are so important, why aren't they on the front of the card?"

In some respects performance monitoring in education and psychology parallels the front and back of my son's baseball cards. All too often we assign the "back of the card" to the "statistics" needed to monitor pupil performance and the effectiveness of the interventions that we as psychologists and educators have crafted. Because we expend considerable effort developing interventions for students in need, the question arises as to why monitoring pupil performance and the effectiveness of our interventions frequently takes a back seat to other activities. The question is important because performance monitoring is a primary ingredient in the problem-solving approach (Iowa Department of Education, 1991).

> Progress monitoring is an essential aspect of any systematic approach to solving student problems. Whenever an intervention is implemented, student performance data should be collected on a regular and frequent basis. This on-going progress monitoring will yield objective data describing the student's progress toward goals. The data can be used to make decisions about the relative effectiveness of interventions. (p. 29)

Why is it so difficult to get educators to monitor pupil performance? Explanations for this occurrence fall into two categories. First, those who would monitor pupil performance are confronted with a variety of *external* difficulties and constraints within the educational environment. Second, many of the traditional assessment procedures used for performance monitoring possess *internal* technical problems.

Problems external to the measurement system that influence whether educators or psychologists implement performance monitoring include time constraints (Mirkin, 1980), cost (Mirkin, 1980), and at times, a negative attitude some educators have toward measurement (Bancroft & Bellamy, 1976). Frequently cited objections reported by Bancroft and Bellamy (1976) include

- Teachers think data are not necessary because they believe they already know where students are functioning.
- Classroom monitoring systems sometimes ignore essential characteristics of learning and development.
- The procedures are often too rigid and interfere with instruction.

Several problems internal to the traditional assessment procedures can also be identified. First, the technical adequacy of traditional assessments is often challenged. Ysseldyke, Algozzine, Regan, and Potter (1980) documented that many of the traditional instruments selected for measuring pupil performance do not possess adequate validity or reliability. Second, many available tests are not useful for instruction (Thurlow & Ysseldyke, 1982; Tindal, 1985), and third, in many cases assessments do not match the curricula used for instruction (Good & Salvia, 1988). A fourth problem is that most tests are not sensitive to real student improvement and an edumetric approach must be adopted if student learning is to be measured (Carver, 1974).

In reaction to these external and internal concerns new assessment models have emerged to provide instructionally relevant data to the teacher. Fuchs and Deno (1991) point out that many of these models are rooted in behavioral psychology, such as Individually Prescribed Instruction (Glaser, 1966), Precision Teaching (White & Haring, 1980), and Data-Based Program Modification (Deno & Mirkin, 1977). An ingredient common to these types of models is systematic and objective quantification of behavior, typified by the guidelines Tawney and Gast (1984) described: "Basic steps or rules to be followed in the assessment process include (1) identifying what is to be measured, (2) defining the behaviors or event in observable terms, and (3) selecting an appropriate data-recording system for observing, quantifying, and summarizing behavior." Tucker (1985), in a review of curriculum-based assessment systems, delineated three major characteristics of these new instructionally relevant measurement systems: Use of items from the pupil's curriculum for monitoring, frequent measurement, and use of the data to evaluate instructional effectiveness. Marston and Magnusson (1988) labeled these three constructs as direct measurement, repeated measurement, and time series analysis.

Direct Measurement

Direct observation of student responses is paramount to performance monitoring. The notion of direct measurement fits nicely with Reynolds' (1982) analysis of how assessment is connected to the rights of children: "In general, behavioral assessments should be based heavily on direct observations rather than on presumed predispositional or underlying traits" (p. 105). Proponents reason that listening to a child read or examining a student writing sample is a more direct measure of performance than analyzing student responses on traditional achievement test items such as multiple choice or true/false questions.

The issue of directness is related to the extent to which the unit of measurement in the monitoring system allows one to examine actual student behavior. Johnston and Pennypacker (1993) argue the accuracy of measurement improves when the meaning of a unit of measurement is fixed or absolute. They make the distinction between idemontic units of measurement, whose meaning is absolute, and vaganotic units, where meaning varies. Idemontic units have a consistent form that makes observation from situation to situation more accurate. Vaganotic units, however, can differ across observations, meaning lowered reliability. Thus, observing idemontic units of behavior such as "words read correctly" or "letters correctly identified" is more accurate in monitoring performance than using vaganotic units such as "grade equivalent scores," "percentiles," or "Likert ratings."

Repeated Measurement

Another important element in performance monitoring is the use of repeated measurement. Frequently monitoring of pupil performance during the academic year increases the reliability of observation and allows for the examination of trends in student growth and quicker reaction to pupils who are falling behind. This dynamic approach to measuring student improvement exceeds the results of performance monitoring with achievement tests. A brief look at the "educational lifetime" of a typical student who attends school for 13 years (K–12), which is approximately 2,300 instructional days, confirms this. For example, using traditional achievement tests, at the rate of twice per year, means that the progress of the student would have been monitored 26 times during his or her "educational lifetime." However, if pupil progress were monitored on a weekly basis during these same 13 years of instruction, the result would be almost 500 measurements of student growth. Performance monitoring creates the latter condition and provides educators with timely assessment information that improves instructional decision making. The concept of repeated measurement is featured in Nazzaro's (1976) conclusion, "All evaluation procedures have potential biases and any 'one shot' sample of behavior, whether it be a test, an observation, or any other technique, tells little about a person's ability to learn. Only by sampling over time can one gain a fairly accurate picture of a child's potential" (p. 41).

Time Series Analysis

Time series analysis is the systematic examination of a student's direct and repeated measurement data in relation to implemented interventions. At the center of time series analysis is the graph upon which these data are recorded. By repeatedly plotting the frequency or duration of student behaviors the educator can evaluate the effectiveness of his or her strategy. Parsonen and Baer (1992) identify six advantages to be gained through graphic analysis:

1. It is visual, and thereby quick to yield conclusions and hypotheses.

2. Graphs can be quick and easy to make with no more technology than grid paper, pencil and straight edge. However, if the latest computer graphics technology is to be used, then speed and ease are recaptured only after an initial high cost of money, time, and training.

3. Graphing comprises a remarkably wide range of formats, even outside of the latest computer graphics technology.

4. Graphed messages are immediate, enduring, and accessible to students at unusually diverse levels of training.

5. In representing the actual data measured, graphs can and usually do transfer those data as minimally as possible. In those paradigms of knowing wherein the measurable data under study are the reality to be understood . . . , that is an obvious virtue.

6. The theoretical premises underlying graphs are minimal and well known — that what we are in-

terested in can be made visual, and that almost all of us are skilled in responding to visual isomorphisms of the world in ways that make the world useful. By contrast, the theoretical premises underlying the defensible use of statistical analysis are numerous, complex, diverse, and frequently arcane to the majority of their users. Thus, statistical analysis users find themselves relying on techniques subject to apparently endless debate about their suitability for given problems — a debate often accessible to only a small minority of the users.

Use of the graph is critical to time series analysis. However, Tawney and Gast (1984) point out data should not be collected for the sake of just collecting data: It needs to be used in the teacher's decision-making process. This notion is supported by Fuchs and Fuchs (1986) who demonstrated that when performance monitoring scores are graphed rather than recorded, student achievement improves about .5 standard deviations.

BASIC CONSIDERATIONS

Background Information

Many of the principles and concepts behind the performance monitoring approaches described in this chapter are grounded in applied behavioral analytic procedures theory. While not a requirement, a knowledge base in this area would obviously assist the school psychologist implementing performance monitoring procedures in the areas of inservice training, consultation and problem solving, and the development of new systems. Background sources that describe behavioral theory and single subject analysis include Kratochwill and Levin (1992), Johnston and Pennypacker (1993), and Tawney and Gast (1984).

The elements of performance monitoring presented here are found in the early work of Deno and Mirkin (1977) and are updated in Deno (1986). More recently, Fuchs and Deno (1991) clarified the role of Curriculum-Based Measurement when they examined instructionally relevant measurement models and identified two major models: specific-subskill-mastery measurement and general-outcome measurement. In the specific-subskill-mastery measurement model, general educational goals for the student are broken down into sets of subskills matched to short-term instructional objectives. Measurement in this model thus focuses on student performance on small sets of items specific to each objective. Thus, performance monitoring procedures are specific to the units of instruction and tend to be short term.

Fuchs and Deno (1991) note that while this approach provides flexibility and the opportunity to focus on specific instructional objectives it creates two problems. "First, freedom to select among a wide variety of alternatives resulted in ad hoc and idiosyncratic measurement with unknown reliability and validity. Second, the short-term objective focus of the mastery measurement did not prove useful for answering broad questions about student growth, such as 'How effective is my instructional program (a) in producing growth over time, or (b) in comparison to other instructional strategies I might have used with this child?'" (p. 489).

General outcome measurement procedures developed by Deno and associates were designed to solve these problems and answer these questions. To do so these researchers created a methodology of performance measurement that (a) prescribed the critical behaviors and procedures for monitoring and (b) could be used for long-term goal measurement, such as an academic year. The practices described in the next section conform to this *general-outcome measurement* model.

Equipment

Materials and equipment needs for implementing the performance monitoring approaches described in this chapter are minimal. Any school psychologist with access to the district's curriculum and a knowledge of district objectives can begin to create the materials necessary for monitoring. In addition, there are some commercially available products that would assist in measuring performance and graphing data.

Training

A key ingredient to the success of performance monitoring is training. The authors' experience has demonstrated that the traditional one-day workshop is not enough for training educators to begin and maintain implementation. Beyond initial training, learners need follow-up consultation on a regular basis. In the Minneapolis Public Schools, once-a-month meetings with lead teachers are provided throughout the school year after the initial one-day workshop.

Training should emphasize a conceptual understanding of the model and stress reliability during the implementation of procedures. The Minneapolis schools' training focuses on the rationale, the need, and the research basis for direct, repeated measurement and graph analysis. Once a philosophical framework is established, consistency and reliability in administration of procedures should be stressed. During initial training, an interrater agreement above 90% should be required for new trainees, with follow-up consultation and examination of reliability provided to avoid any drift away from standard practices.

BEST PRACTICES

Tawney and Gast (1984) have identified a sequence of important steps essential to any valid performance monitoring system:

1. Define the target behavior in observable terms.

2. Collect data only to the extent that the data will be used to guide instruction, that is, avoid the trap of collecting data on all programs and behaviors.

3. Measure that aspect of a student's objective which is of interest, that is, do not restrict data collection to simple responses and ignore more interesting and important aspects of student behavior.

4. Become thoroughly familiar with data collection and research design alternatives.

5. Select a measurement system which is practical and which can be consistently and reliably used within the constraints of the classroom.

6. Structure the classroom (daily schedule, staffing assignments, etc.) to facilitate data collection as well as teaching.

7. Evaluate data regularly and base instructional decisions so as to maintain or modify the program on the data.

8. Collect performance data frequently to yield an accurate measure of program effectiveness.

This section presents three examples of "best practice" in performance monitoring. These models conform to the basic principles set out by Tawney and Gast (1984) and are derived from the Curriculum-Based Measurement approach described by Deno (1986). These approaches include analyzing individual student growth in the Minneapolis Public Schools (Marston & Magnusson, 1988), analyzing classroom growth at Vanderbilt University (Fuchs, Fuchs, Bishop, & Hamlett, 1992), and performance monitoring in content areas at the University of Oregon (McCollum, Tindal, & Nolet, 1992).

Performance Monitoring: Analyzing Individual Student Growth

Performance monitoring has been an important component in the delivery of services to special education students in the Minneapolis Public Schools. Since 1983 the K–6 Resource Program has used Curriculum-Based Measurement (CBM; Marston & Magnusson, 1988) to continuously evaluate the impact of instructional interventions and measure progress toward the goals of the Individualized Education Program (IEP). An example of this type of performance-monitoring system is shown in Figure 1 which illustrates direct, repeated measurement and time-series analysis of pupil progress. For this student, Jason, CBM reading probes have been administered weekly during the school year. Jason's performance is plotted on an equal interval graph. Weeks are shown along the horizontal axis; the words read correctly are charted along the vertical axis. During "Phase A" instruction, it is clear that the reading progress of this second grader is minimal. However, during "Phase B" reading instruction, the student improves considerably.

How to develop probes. Because repeated measurement is essential to the performance-monitoring model, many equivalent probes must be created. In the Minneapolis schools, at least 30 different, but approximately equal, reading passages have been developed for each grade level. Passages are at least 200 words long and typed onto separate pages. The *student copy*, from which pupils read, contains only the text; the *examiner copy* includes a cumulative word count for each line to aid in scoring.

How to administer and score the probes. Students are asked to read aloud for 1 minute. During that minute the student is to attempt each word. If the student cannot correctly identify a word within 3 seconds, he or she is prompted to continue. The examiner follows along on the examiner copy and marks with an "X" those words incorrectly pronounced or omitted; self-corrections are scored as correct. At the end of the minute, the examiner counts the number of words read correctly. An interrater agreement coefficient of at least .90 is required during teacher training.

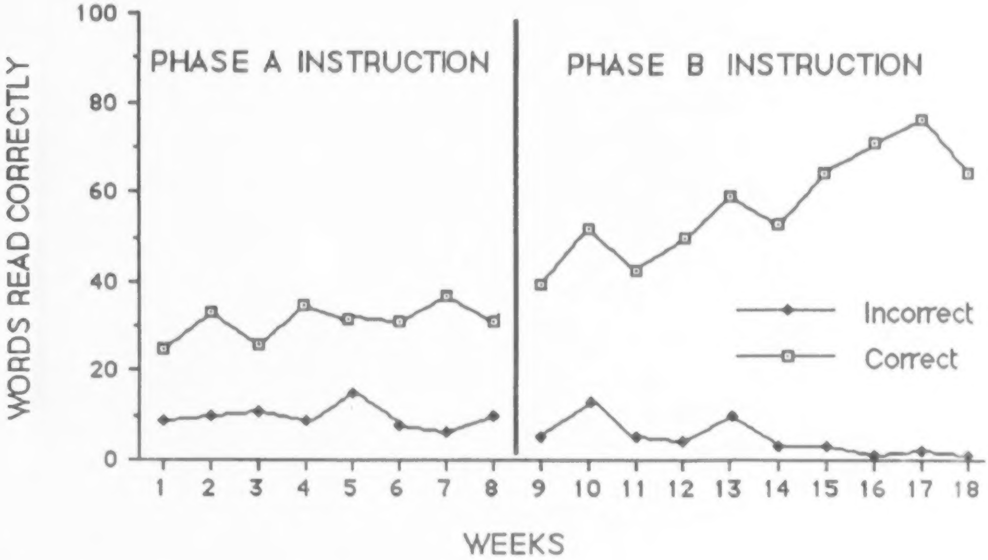
How to determine an appropriate measurement level. The next task in performance monitoring is the selection of the level of passages in which monitoring will occur. Let's assume that Jason, a sixth grader in need of special education, is instructed in a third-grade book. If a sixth-grade book were selected for performance monitoring, Jason would probably find the probes too hard to read. Most likely his scores would be close to the bottom or *floor* of the graph and the monitoring system would not be sensitive to pupil growth (White & Haring, 1980).

On the other hand, if we use Jason's third-grade reader, material in which he is receiving instruction, his scores may be toward the top or *ceiling* of the graph because of practice. The *ceiling effect* attenuates growth during performance monitoring.

Deno, Mirkin, and Wesson (1984) provide a procedure for eliminating floor and ceiling effects. They suggest a *sampling back* process in which observers listen to the pupil read in successively easier grade level readers. Marston and Magnusson (1988) provide empirical guidelines. For first- and second-grade students a reading level in which the student reads 10 to 30 words correctly per minute should be used for performance monitoring. The criteria for third to sixth graders is 30 to 60 correct words.

How to select a graph. Before plotting the student's performance the type of graph upon which it will be plotted needs to be selected. For most purposes the simple equal interval chart should be used. On this chart, time is measured along the horizontal axis and performance is scaled along the vertical axis.

FIGURE 1. An example of direct, repeated measurement and time-series analysis with Curriculum-Based Measurement procedures.



Precision-teaching proponents prefer the semi-logarithmic graph where performance along the vertical axis is measured on a logarithmic scale (White & Haring, 1985). Marston (1987), however, compared both types of graphs and found predictions of goal attainment were more accurate with the equal interval chart. He notes that this type of chart also possesses the advantage of easier communication with parents and other educators when discussing pupil performance .

Johnston and Pennypacker (1993) also provide relevant information on constructing graphs. These authors discuss how data ought to be presented, which measurement scales should be used, and the rules governing how a scale is applied and how data ought to be plotted.

How to set the long range goal. Once the measurement material for performance monitoring has been selected, it is time to set a goal and begin. The following paragraphs describe three approaches for determining the student goal:

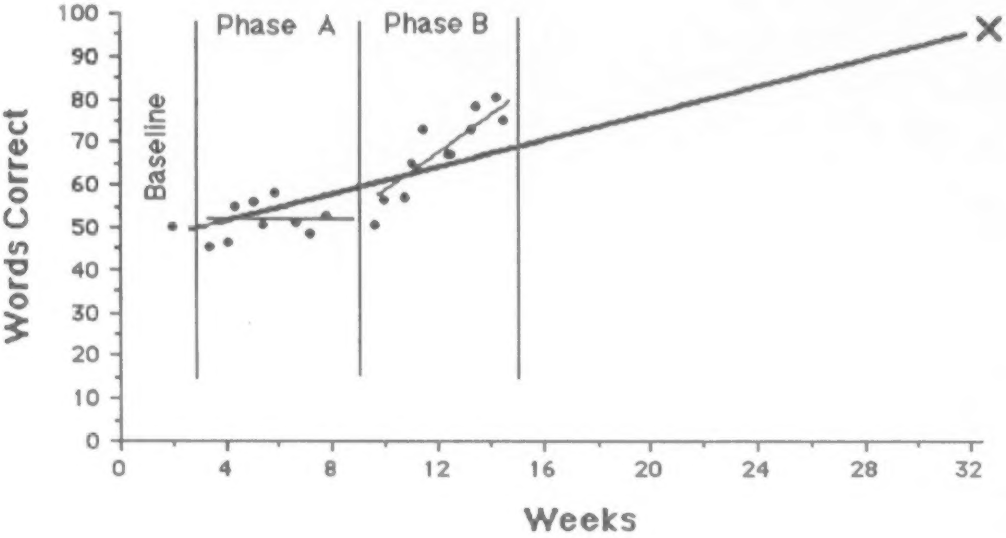
1. **Normative tables.** A normative database was compiled in Minneapolis schools from testing approximately 7,200 students in Grades K–8 during the Fall, Winter and Spring of an academic year. The data provide percentile ranks for each grade level for every month from September to June. This allows teachers to determine the typical performance at any level during the school year, and helps them select an appropriate goal for an individual student.

2. **Average learning rates.** Minneapolis has also examined hundreds of student charts in an effort to determine the typical learning rate of pupils at every grade on the various CBM measures. These rates can be used to set goals. For example, Minneapolis data demonstrate that each week the average first- and second-grade resource student gains about 1.5 correct words per minute (cwpm). Resource students in third to sixth grade improve about 1.0 cwpm per week. General education students, however, have higher weekly slopes: first and second graders improve 2–3 cwpm per week while third to sixth graders increase at about 1.5–2.5 cwpm per week. With this *average learning rate* database, teachers can determine goals by multiplying the number of weeks left in the school year by the selected weekly gain and add this to the student's baseline level.

Mastery criteria. A review of mastery criteria research by Fuchs (1982) and Starlin and Starlin (1974) indicates that appropriate goals are from 50 to 70 correct words for Grades 1 and 2, and 70 to 100 words correct for Grades 3 to 6.

How to use data-utilization strategies. Once the monitoring level is determined and a goal is set, performance monitoring is ready to commence. The question now is which type of data-utilization rules to use. This is important, because application of rules to time-series data significantly increases its usefulness in helping determine when to make changes in interventions. Fuchs and Fuchs (1986) have established that a .91 standard deviation increase in student achievement is associated with the systematic use of data-utilization rules.

FIGURE 2. An example of trend line analysis.



The Minneapolis Public Schools used two sets of rules: *trend-line analysis* and *data-point analysis*. In both approaches evaluations of intervention effectiveness are based on progress toward the goal.

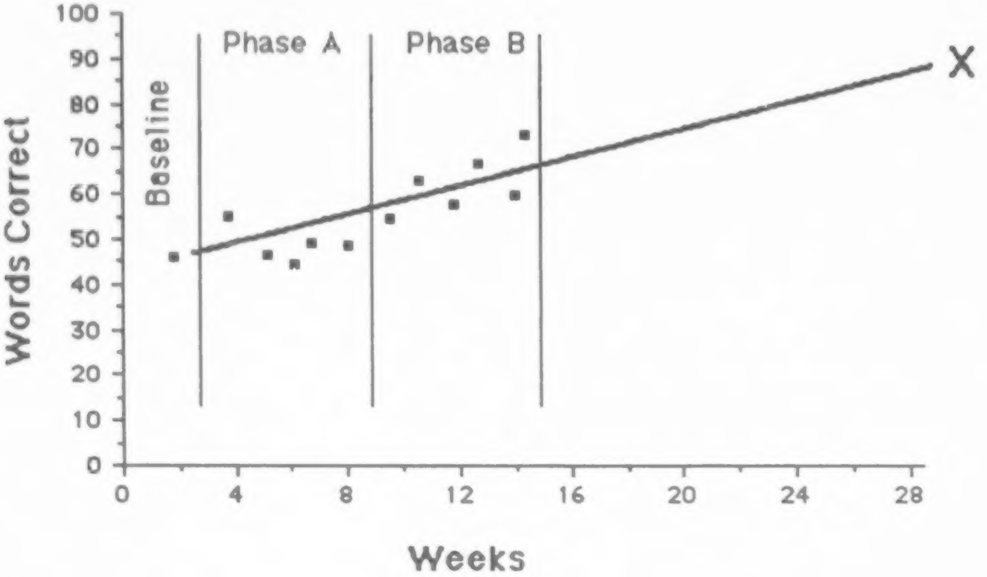
- **Trend-line analysis.** Trend-line analysis uses the trend line or slope of the data points and is calculated by White and Haring's (1980) Quarter-Intersect method. After 9 to 12 data points are collected, typically 3 to 4 weeks of data collection, the trend line is drawn. If the trend line is higher than the aim line, only minor changes, if any, to the program should be considered. However, if the slope is lower than the aim line, major changes in the intervention are warranted. For example, the trend line in Figure 2 Phase A instruction indicates that the instructional program is not successful and a major change needs to be made. The trend line in Phase B, however, is higher than the aim line and indicates only minor modifications should be made, if at all.
- **Data-point analysis.** In data-point analysis no trend line is drawn. Instead, individual data points are analyzed in relationship to the aim line. These data points typically represent the median of three passages read during a week of instruction. If four consecutive data points fall below the aim line, a change in the instructional intervention should be made. Similar to trend-line analysis, it takes approximately 4 weeks to collect enough data to make a decision about instituting instructional changes. In Phase A of Figure 3 four consecutive medians fall below the aim line, indicating a need for change. However, in Phase B, the student's reading medians fall above and below the aim line in equal fashion. In this case the intervention would continue as implemented.

Recent research by Fuchs, Fuchs, and Hamlett (1989) indicates higher levels of student achievement will occur if goals are increased during the school year. In this type of *dynamic* system of data utilization, teachers raise the student's goal if certain conditions are met. As a result the procedures correct for goals that might initially be set too low due to low teacher expectations, errors in measurement, or the like. In fact, Fuchs, Fuchs, and Hamlett (1989) found that "despite the importance of ambitious goals, special educators' typical goal-setting standards may under estimate many students' potential" (p. 436). This dynamic approach dictates that after a specified period of time, the teacher must make some type of change, either by raising the student's goal or making an instructional change.

Performance Monitoring: Analyzing Classroom Growth

Fuchs et al. (1992) have modified CBM procedures, which are typically used for individual assessment, for class-wide monitoring purposes. Relying on microcomputer technology, these researchers at Vanderbilt University have developed math and reading probes that can be used to monitor performance and help evaluate general education interventions in the classroom. They reason that while CBM is effective for evaluation at the individual level the diversity of public school classrooms demands assessment procedures that are useful for entire classrooms. "Unfortunately, despite the demonstrated efficacy of CBM within special education programs, few studies have

FIGURE 3. An example of data point analysis.



investigated the capacity of teachers to use this assessment methodology to design more effective programs within general education" (Fuchs et al., 1992, p. 40).

These reviewers created a set of equivalent monitoring probes that were keyed to basic math operations of addition, subtraction, multiplication, and division of whole numbers, fractions, and decimals. Each probe included 25 problems and was designed to be administered twice monthly by the teacher in a whole-class format or administered to the student working at a microcomputer setting. The computerized format offers several advantages: "The computer scores the test, keeps track of student mastery over time on the different skills incorporated in the annual curriculum, provides student feedback, and aggregates information across students to describe for teachers the class performance and to provide teachers with instructional recommendations" (p. 42).

The computerized performance-monitoring system provides individual feedback in the form of student growth, similar to those described in the previous section, and mastery feedback on specific skills for each student such as: adding with regrouping; subtracting with regrouping; subtracting with regrouping using 0; multiplying basic facts; multiplying 2-digit by 1-digit number with regrouping; and dividing basic facts. The computer also generates class-wide teacher feedback in graphic and mastery form. On the class-wide graph the 25th, 50th, and 75th percentiles are plotted twice each month. As a result, the teacher is able to examine typical growth at each percentile over the entire year. The class-wide report also presents a student list to show the degree to which a variety of skills have been mastered. Further, the report identifies groups of students for each skill area that need further instruction.

Research on this approach with students in Grades 2 through 5 showed that general educators were satisfied with the monitoring system and that "achievement data indicated a main effect (across different types of learners) favoring the growth of the students whose teachers used CBM with classwide reports that included instructional recommendations over each of the other conditions" (Fuchs et al., 1991, p. 49). They concluded that class-wide CBM decision-making was useful for general educators in planning for a wide range of students.

Performance Monitoring: Measurement in Content Areas

The ideas presented in the last two sections demonstrated how performance monitoring can be implemented for basic skills at the individual and classroom levels. This section provides some new ideas from the University of Oregon on how to monitor student performance in "content" areas using the principles of direct measurement, repeated measurement, and time-series analysis (McCollum et al., 1992). According to these authors, instruction and assessment in the content areas can be linked, providing continuous information about student progress. Problem-solving essays are used to assess the student and his or her ability to use the knowledge forms, concepts, or principles, in one of six intellectual operations: (a) reiteration, (b) summarization, (c) illustration, (d) prediction, (e) evaluation, and (f) application. A prompt is provided which poses a problem the student must solve by drawing on his or her understanding of specific knowledge forms. This same type of questioning and problem solving can be included in the instructional format so students are practicing using information in the service of solving some problem. Achievement is then based on the student's ability to manipulate the learned information. This type of classroom-based assessment, which links measures of performance with instruction, can be used to determine if the students have learned what the teacher wanted them to learn. Therefore, posing problems to students that require the use of intellectual operations becomes not only an important part of instruction but can be used in lieu of a typical assessment measure: It indicates meaningful use of information and success in instructional content.

Before instruction begins, the teacher reviews the material to be covered and identifies key *concepts* to be taught. Concepts are specific words or short phrases that refer to classes of objects or events sharing some common defining attributes. Concepts involve three parts: a label, key attributes, and a range of examples. For each concept, the teacher identifies key defining *attributes*, which enable discrimination of what is and is not an example of the concept. Examining the extent to which the student uses the concepts and attributes is critical to the assessment process. In addition, student essays are examined for the number of *thought units* expressed in the written composition.

In the case study presented here, Tom is a Chapter I student who is part of a seventh-grade social studies class. Instruction was designed to directly teach concepts and attributes related to (a) the geography, (b) the political systems, and (c) the economy of Greece and Rome. Significant emphasis was placed on examples and non-examples where the examples focused the students' attention on the dimensions of a concept, while non-examples acted as a means of discrimination. Principles were discussed and applied in different contexts. Graphic organizers were periodically used to provide a framework for teaching concepts and attributes in a simplified structure for delivering information and to assist the students in noting relationships among concepts and principles.

Every effort was made to challenge the student to think and draw on his knowledge and experience of a specific concept or principle. The student was provided repetitive instruction until a solid understanding of a concept or principle was gained, and then an effective questioning strategy was applied that prompted the use of information and personal background knowledge to solve a problem with some relevance to life and historical patterns. The result of this process was a student motivated to think and respond.

Student performance was assessed by analyzing work products and ascertaining their presence. As mentioned previously, an opportunity to practice using intellectual operations to manipulate knowledge forms was used as part of instruction. This practice resulted in a number of subproducts, or problem-solving essays, written by the case students over a 2-month period. Once Tom had an understanding of the critical concepts, he was asked to respond to a number of prompts that required the manipulation of knowledge forms in some intellectual operation.

In the following subproduct collected at the beginning of the instructional period, Tom was asked to make some decision and explain his reasoning about some specific concepts, in this case political systems. Although a decision was made, he gave minimal explanations for the concept selected.

- **Subproduct Prompt #1** — A group of people in one area of an empire are dissatisfied with the harsh rule of their king. They do not want their lives ruled by this strict king, but feel the need for some type of system (government) to help make decisions and solve problems for the people. What political system might they try to develop (assuming the king agrees)? Tell why that system (or government) would be better than the current rule by a king.

- **Tom's Written Response to Prompt #1** — *They might try to make a republic.*
  Because a king cant have his spot taken and you dont vote for king.
  if the elected person gets mouthy you can fire him republic people are involved

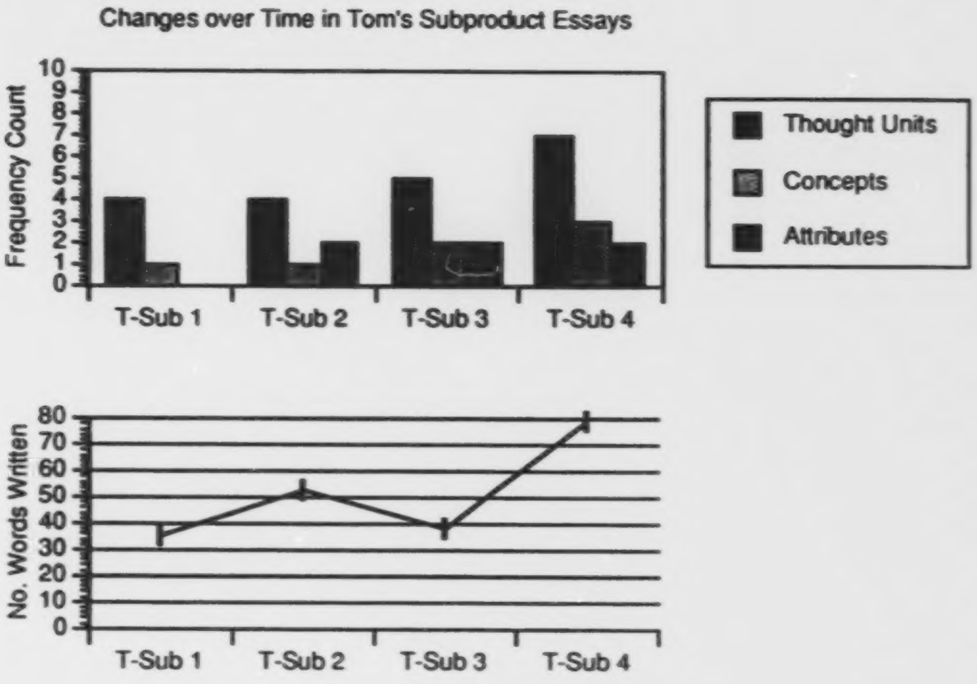
The essay was designed to reflect evaluation responding and Tom made a choice based on his knowledge of the concepts. He then attempted to make an argument for his choice, although his knowledge of the concept of republic is expressed in too vague a manner (don't vote for king/republic people are involved). This composition was scored as having 4 Thought Units, 1 Concept, and 0 Attributes. Tom wrote 35 words.

Toward the end of the 2-month instructional unit Tom responded to the following Subproduct Prompt.

- **Subproduct Prompt #2** — You are a merchant with a spice store in the township of Chestwick in the late Middle Ages. Many of the merchants in Chestwick have seen how well a charter has helped the people in the neighboring township and want to try this new system of self-governing. What happened to cause this movement toward writing charters in the late Middle Ages?

- **Tom's Written Response to Prompt #2** — *The early Middle ages. because the people were all was bosed around by the vassels, nobles. And so then they would want a charter so they won't get bosed*

FIGURE 4. Performance monitoring in content areas.



Changes over Time in Tom's Subproduct Essays

around. because they wanted to sell what they wanted to sell and sell it for the price they wanted to sell it, live where wanted. Becaus the loards don't know what there talking about as far as trade or the merchants buisnes|m|mthey want a charter so the can run themselfs.

In this composition Tom had 7 Thought Units, 3 concepts, and 2 Attributes, while writing 80 words.

The charts in Figure 4 depict Tom's performance over time. In the top graph, the number of thought units (one thought unit being a complete thought that could stand alone), concepts, and attributes are counted for each of Tom's subproduct responses (T-Sub 1–4). The bottom graph indicates the total number of words written for each subproduct response.

Notice that the number of thought units increases as Tom gains experience in responding to essay prompts. Also, his use of concepts within essays increases. Where the first two essays contain only one concept, subsequent essays contain an increase of one concept. Also, where concept attributes are nonexistent in the first essay, later essays contain more than one attribute. In the bottom graph, the number of words increases despite a decrease for the third essay response. Although Tom has used fewer words in this response, the essay contains the use of two concepts and two attributes and indicates a clear understanding of both. Many students' essays contain much superfluous information and indicate no truer understanding. Data for Tom indicate improvement in use of critical information for written responses.

Research on Barriers to Implementation

Yell, Deno, and Marston (1992) examined barriers to the implementation of performance monitoring with CBM procedures. They surveyed special education administrators from around the country using Delphi Probe techniques and identified the 10 greatest concerns:

1. Lack of repertoire of instructional strategies to use when data indicate teachers need to make an instructional change.

2. The practice by some teachers of mechanically measuring and charting but not using data to make instructional decisions.

3. Resistance to change: The use of CBM represents change and trying to implement change brings about resistance and anxiety.

4. Ongoing training system for special and regular education staff.

5. Applying CBM in secondary schools.

6. The logistics of evaluation and modification.

7. Difficulty in getting staff to use CBM to adjust their instructional strategies.

8. Time needed to monitor teacher's implementation of CBM.

9. Adequate district human resources to fully implement the program.

10. Concern over words read per minute, and if this realistically measures comprehension.

The first author's experience in the Minneapolis Public Schools is similar in many ways, particularly, barriers 1, 2, and 7. After Minneapolis first implemented performance monitoring, it was discovered that although the teachers were graphing student data, they made on the average approximately one instructional change per year in reading. Several reasons emerged as to why the student graphs showed few instructional changes. First, some teachers were unclear as to what constituted an instructional change or how significant a change should be to merit recording it on the graph. Second, some instructional changes for students may have been made independent of the data and not recorded on the graphs. For example, a teacher might react to the performance of one or two students in an instructional group and make a change for that entire group. Finally, in some cases it appeared that teachers did not make instructional changes because they were not equipped to provide an alternative.

The solution to this later problem was to increase inservice training on a variety of instructional interventions. Other approaches to countering barriers 1, 2, and 7 included pairing teachers with instructional specialists to discuss strategies or provide teachers with a forum to periodically discuss their data with other special education teachers. These "chart-share" sessions allowed teachers the opportunity to develop innovative ideas on how to teach individual students.

Time, barrier #8, is another frequent barrier but three approaches can help. First, teachers need to organize their materials in such a way that one-to-one monitoring of students can be conducted while other students are engaged in important instructional behaviors (Wesson et al., 1986). Second, teachers can decrease their standardized achievement testing, which makes more time available. Third, time for implementing the monitoring system in Minneapolis was decreased by changing to the data-point analysis approach. In this method three weekly probes are administered on the same day and the median is plotted. In addition, trend lines are not drawn, another time saver.

Many of the barriers to implementation of performance monitoring can be overcome by providing ongoing training activities and follow-up visits. For further discussion of ideas see Yell, Deno, and Marston (1992).

SUMMARY

Performance monitoring "statistics" should not take a back seat in educational practice. The measurement of pupil progress on an ongoing basis provides the educator with an opportunity to evaluate intervention effectiveness and truly link assessment to instruction. When such systems help guide instructional practice the assessment data is viewed as more meaningful. Further, such systems improve the skills of the school psychologist in his or her consultative roles.

To create the link between assessment and instruction, performance-monitoring procedures first need to be direct; that is, important academic behaviors ought to be directly observed so that accuracy and validity can be ensured. Second, assessment needs to be conducted on a repeated basis, rather than once or twice a year. Time is precious and educators can ill afford to wait to evaluate the effectiveness of the interventions. Third, time-series analysis can examine the relationship of student growth on direct, repeated measures of behaviors with the instructional interventions.

By implementing performance-monitoring procedures based on these three concepts the school psychologist has gained an important tool for improving the effectiveness of educational interventions with students. The practices described here can be used at the individual or classroom level of analysis. Further, these procedures, which were initially developed for basic skill areas, have been extended to content areas. Finally, barriers to implementation are described and some solutions presented. Attention to these issues will enhance the school psychologist's prospects for successfully implementing performance-monitoring procedures at the individual or systems level.

Best Practices in School Consultation

Joseph E. Zins
University of Cincinnati

William P. Erchul
North Carolina State University

OVERVIEW

Consultation has become one of the primary job functions of many school psychologists. This trend in practice is supported by a mounting body of empirical evidence demonstrating the efficacy of consultative services (e.g., Medway & Updyke, 1985), although there continues to be great need for further research on all aspects of the process.

Our goal in this chapter is a very practical one. We intend to present essential information about what a school psychologist needs to do to be an effective school consultant. Although considerable theoretical and empirical literature is cited, we have no aspirations about providing a thorough review of it, as such information is available elsewhere (e.g., Erchul, 1993; Zins, Kratochwill, & Elliott, 1993). Further, we assume that most readers already have at least an introductory-level understanding of consultation. For those who wish more detail than can be provided in this brief discussion, several recommended references are listed in the annotated bibliography at the end of the chapter.

The chapter begins with a presentation of our conceptualization of consultation, along with the prerequisite competencies and assumptions underlying practice. Next, practical guidelines for best practices in consultation are discussed, including a description of the consultative problem-solving process, and of individual and organizational factors that may exert influence. Finally, several emerging areas of practice are presented.

BASIC CONSIDERATIONS

Several approaches to consultation frequently employed in the schools have been described in the literature, namely, the behavioral, mental health, and organizational. Although universally accepted definitions for these approaches do not exist, and the models were not specifically developed for practice in the schools, the approaches have a number of elements in common. For instance, all stress the use of problem solving as the mechanism through which consultative interventions are developed, focus on work-related problems, and view participation in the process as voluntary. However, they differ in aspects such as the roles and relationships of consultants and consultees, the focus of consultative interventions, and the organizational level at which they are implemented. Despite the differences and lack of agreement in definition, the approaches are more similar than different, and consensus is emerging regarding key elements of the process (Zins et al., 1993).

The approach to consultation described in this chapter borrows heavily from a variety of models, but theoretically is most closely aligned with the ecobehavioral approach, which combines the behavioral and ecological/systems paradigms (Gutkin, 1993). It emphasizes the application of behavioral technology and utilization of the broad-based ecological/system perspective. We have extended the most salient aspects of a number of prior works, added some new ideas, and synthesized this information into a coherent framework specific to practice in the schools. Schools are different from other settings such as hospitals, correctional facilities, or business organizations, and because context is such an important aspect of consultation, it is desirable to limit the focus to school consultation. Such an approach also provides the latitude to discuss the various types of consultation that occur within schools, including consultation with individual teachers and parents, with groups of consultees, and systemwide consultation directed toward changing entire educational organizations.

Definition of School Consultation

In this chapter, school consultation is defined as a method of providing preventively oriented psychological and educational services in which consultants and consultees form cooperative partnerships and engage in a reciprocal, systematic problem-solving

BEST COPY AVAILABLE

process within an ecobehavioral framework. The goal is to enhance and empower consultee systems, thereby promoting students' well-being and performance. A brief explanation of the essential components and underlying assumptions of this definition follows. Although ideas from many sources form the basis of this discussion, it is difficult to attribute original responsibility for many of the concepts. As Gutkin and Curtis (1990) note, these ideas have by now been so widely discussed that they are part of the basic assumptions typically made about consultation (even though not all have been empirically validated).

Preventive orientation. Consultation has a dual focus. It provides a mechanism through which the presenting problem is remediated, and secondarily, it attempts to increase consultees' skills and alter environmental variables and setting events that elicit and maintain problematic behaviors. These procedures are intended to prevent problems from becoming more severe and additional ones from arising.

The first goal is met by developing specific, empirically based interventions to deal with the presenting problem. The second is accomplished in a less direct manner by (a) ensuring that the consultant's expertise is readily available to the consultee system through encouragement of frequent interactions between consultants and consultees to facilitate the prevention and early identification of problem behaviors; (b) improving consultees' skills and knowledge so they can more effectively address similar problems in the future; (c) maintaining a systems perspective so that the broad array of conditions that might contribute to problem development and maintenance are considered and can be addressed; and (d) developing and implementing primary and secondary prevention programs. According to the literature, in most cases it is necessary for consultees to solve several problem situations successfully with the consultant's assistance before they apply these procedures independently, as training to a single exemplar is ineffective as a means of promoting generalization (Stokes & Baer, 1977). Even when consultation is applied in a clearly rehabilitative fashion, a primary intent is to minimize the possibility that more serious problems will arise. In practice, this preventive goal is not accomplished as often or as easily as the first; nevertheless, it should be pursued to enhance the overall value of the consultation process.

The increasingly preventive focus of consultation is gradually shifting the focus from individual children to entire systems — schools, school districts, the larger community, and even relevant state and federal policies, regulations, and legislation (Swift & Cooper, 1986). Practitioners, who are often frustrated by the limitations of focusing interventions on individual children are now recognizing the potential efficacy and long-term benefits of wide-scale interventions (see Knoff & Batsche, 1993, for illustration).

Method to provide services. Consultation is a means by which school psychological services are provided, or what Miller (1969) might describe as another way of "giving psychology away" to nonpsychologists. Indeed, consultation is often the foundation or overarching framework from which all other services are delivered and around which all other services are organized. The goal is to help clients (usually students) and the consultee system. Students are assisted indirectly through the process, in contrast to the direct method of providing service traditionally associated with psychoeducational assessment or counseling. However, we usually do not use the term *indirect* in discussions with educational decision makers because of a concern about the negative connotations that some occasionally attribute to it. These persons may mistakenly believe that all students benefit best from "direct" forms of help, and may not fully understand how consultation actually facilitates the provision of such assistance. Further, even when providing a direct service to a child, consultation with primary caregivers is crucial to ensure comprehensive assessment and treatment.

Cooperative partnership. Consultants and consultees work together to solve problems, and it is highly desirable for them to do so within a relationship that emphasizes trust, openness, and a sharing of responsibilities and expertise. In the phrase "cooperative partnership," *cooperative* implies that (a) participants work jointly on as equal a basis as possible (realizing that their levels of need are unequal and their areas of expertise are often divergent), and that (b) they have different contributions to make and varying responsibilities to uphold to maximize consultation effectiveness. *Partnership* implies that these responsibilities are clearly specified and mutually agreed upon to facilitate progress toward common goals.

In terms of specific responsibilities, consultees must provide contextual ecological information to help define problems and develop interventions. They also must assist in determining what interventions can be implemented in their setting and within their repertoire of skills. Both participants have responsibility for defining and analyzing problems, for establishing and maintaining the cooperative partnership, and for conducting follow-up activities.

Although consultants and consultees both contribute to problem solving, the consultant structures and guides the overall process, while consultees supply much of the content of the discussion. Consultee attempts to control the direction of the initial consultation interview have been linked to a variety of negative outcomes (Erchul & Chewning, 1990). However, because consultees (a) retain responsibility for the client, (b) can best judge treatment acceptability, and

(c) usually implement most interventions and thus can ensure treatment integrity, they make the final decisions regarding intervention implementation. Because the latter point is also a potential problem (Gutkin & Conoley, 1990), it is incumbent on consultants to work with consultees to ensure that these decisions are made in an informed and carefully thought-out manner. Finally, the consultant has primary (but not sole) responsibility for (a) ensuring that the atmosphere remains nonevaluative, (b) identifying and presenting interventions for possible implementation in many cases, and (c) developing the evaluation plan. Given these different responsibilities for consultees and consultants, a complementary and interdependent working relationship is needed.

The importance of the cooperative partnership is illustrated in a study by Erchul, Hughes, Meyers, Hickman, and Braden (1992), who studied 61 school consultant-consultee dyads. These researchers found that the more the consultant and consultee agreed on their respective roles, as well as on the process and goals of consultation, the more positive were consultee evaluations of various consultation outcomes, including consultant effectiveness. Although Erchul et al. used the term *teamwork* to characterize the nature of the desirable consultative relationship, their conceptualization is consistent with the cooperative partnership described here. In sum, in a cooperative partnership the possibilities that more creative solutions to problems will emerge are increased, consultee ownership of the intervention plan and commitment to carrying it out are enhanced, and consultee self-efficacy is improved.

Reciprocal interactions. The principles regarding the reciprocal nature of consultative interactions are derived from Bandura's (1977) social learning theory and philosophy of reciprocal determinism. Indeed, these two paradigms serve as a "meta-theory" underlying consultation practice (Zins, 1988). Unidirectional influence approaches usually have predominated descriptions of the interactions between psychologists and those they seek to assist (Tyler, Pargament, & Gatz, 1983), but they do not adequately reflect the complexity of the consultation process. According to Bandura's model, consultant, consultee, and student functioning result from the continuous and reciprocal interactions among behavioral, personal, and environmental factors. During the interpersonal exchanges that constitute consultation, participants exert influence on one another, and their personal perspectives and behaviors usually are altered as a result (Reardon, 1991). The challenge for consultants is to maintain a cooperative partnership while at the same time exerting interpersonal influence. Consultants accomplish this goal by establishing an atmosphere of mutual respect and trust, and by moving the process along through appropriate interviewing techniques. Consultees influence consultants primarily by specifying the assets and constraints of their role, the students, and the setting. Students likewise influence consultants and consultees as well as the entire system. "Therefore, understanding and changing the functioning of a consultee or clients must focus on the interlocking relationship of these three [behavioral, personal, and environmental] factors, not on a single dimension" (Brown & Schulte, 1987, p. 283).

Systematic problem-solving process. Problem solving proceeds through an orderly, systematic sequence of steps as discussed in detail later in the chapter (see Table 1), and the process is dynamic, evolving, flexible, and cyclical in nature (Kurpius & Lewis, 1988). The consultant guides the overall process, but the active joint involvement of all participants is essential to maximize the potential for successful solutions to be developed and implemented. Moreover, formal, written documentation is kept regarding intervention development and outcomes to foster follow-up efforts and to increase accountability.

Ecobehavioral perspective. The behavioral paradigm has dominated the consultation field in recent years, but ecological/systems theories are now offered as means of expanding traditional behavioral approaches (Gutkin, 1993). Both make important contributions to understanding the process.

Behavioral theory provides the experimental rigor and methodology necessary to concisely identify and measure problems, analyze forces influencing problem situations, and evaluate intervention outcomes. In addition, there is an extensive array of behavioral interventions with documented success available for implementation through the consultation process (Elliott & Busse, 1993).

Ecological and systems perspectives offer a useful framework for more broadly conceptualizing the setting or organizational context in which consultation occurs, and they expand the goals of traditional case-centered consultation. The connection between a problem and the system variables that may be contributing to it or preventing its resolution must be examined. This perspective widens the focus beyond the individual child to also include peers, family, teachers, classrooms, curricula, schools, community, other system levels, and so forth. Consequently, a wide array of factors that may be contributing to the problem are always considered in identifying problems and in developing interventions.

Means of empowerment. The empowerment philosophy in consultation "requires different assumptions and behaviors on the part of the consultant than does traditional case-centered problem solving" (Witt & Martens, 1988, p. 213). This ideology recognizes more explicitly that consultees and con-

TABLE 1
Consultative Problem-Solving Process

1. **Establishment of Cooperative Partnership**
2. **Problem Identification and Analysis**
   Define problem in behavioral terms and obtain agreement with consultee.
   Collect baseline data regarding problem frequency, duration, and/or intensity and conduct task analysis as needed.
   identify antecedent determinants of the problem behavior.
   Identify consequences that may maintain the behavior.
   Assess other relevant environmental factors.
   Identify all available resources.
3. **Intervention Selection and Development**
   Brainstorm range of possible interventions.
   Evaluate the positive and negative aspects of the interentions.
   Select intervention(s) from the alternatives generated.
4. **Intervention Implementation, Evaluation, and Follow-up**
   Clarify implementation procedures and responsibilities.
   Implement the chosen strategy.
   Evaluate intended outcomes and any side effects.
   Program generalization, plan maintenance, and develop fading procedures as appropriate.
   Recycle and follow-up as necessary.

sultee systems already possess or can readily develop most competencies necessary to deal with student-related problems, given the right opportunities and knowledge of available resources (Rappoport, 1981). They have a basic level of competence, but not necessarily the technical knowledge or skills to solve a particular problem. Thus, consultees' failure to solve problems is often a reflection of the system's failure to create opportunities or to provide support for them to exhibit these skills, rather than only an indication of their lack of knowledge about how to deal with the problem. The implications for consultants are significant. Their role becomes one of helping consultees to clarify needs and locate resources, and of ensuring that opportunities are available to enable consultees to engage in self-sustaining behaviors to resolve problems.

Enhancement of student well-being and performance. Although consultation usually focuses on improving consultees' skills and performance or changing their behavior, the ultimate beneficiary is always intended to be the student. To arrive at this goal, however, it is often appropriate for the entire school district or some segment of it to be the initial target of change, as in an organizational development program.

Other characteristics implicit in definition. The problems addressed are always work- or caregiving-related rather than personal. In addition, material discussed is considered confidential by consultants, consultation is entered into voluntarily by consultees, and the relationship is temporary. Gutkin and Curtis (1990) have discussed these issues as well as other core characteristics of consultation in great detail.

Prerequisite Competencies and Assumptions of Consultation Practice

In addition to a general knowledge of psychological principles and techniques (e.g., human learning, ethics, social bases of behavior, research methodologies), there are other prerequisites to consultation practice.

Prerequisites and competencies. A sense of self-awareness with respect to one's feelings, beliefs, thoughts, and impact on others and personal clarity regarding one's values and theoretical biases are helpful to consultants (O'Neill & Trickett, 1982). Because a large aspect of the consultation process involves interpersonal interaction and influence, consultants must be cognizant of their own interpersonal styles, biases, and values, and of how these can impact consultees and influence problem solving.

Similarly, good interpersonal and communication skills are critical because consultation relies heavily on the interpersonal influence process to accomplish its goals. Consultants need, for instance, to be active listeners and to utilize effective questioning techniques to extract necessary information from consultees and to develop clear conceptualizations of problems. Further, the establishment of warm, caring, and understanding relationships is as important in consultation as it is in counseling.

Knowledge of intervention technology, both individually and organizationally focused, likewise is an essential competency, but one that has been largely neglected in the consultation literature. Gutkin (1981) found that over two-thirds of the reasons consultees sought assistance were related to their lack of knowledge and skills in resolving problems, although he did not use an empowerment framework for categorizing these reasons. The implication is that process skills are important but not sufficient for resolving most issues in consultation. Problem-solving and applied behavior analysis skills are also critical. Further, the goal of consultation is to promote application of effective interventions by consultees. Unless consultants are successful in this endeavor, schools will be less likely to use this technology to benefit students, no matter how potentially effective it is (Wolfe, 1978).

An understanding and knowledge of organizations and of organizational functioning is necessary for an ecological/systems perspective. Too often, school psychology training and daily practice tend to focus on the assessment and remediation of individual student-related problems, and consequently do not attend to more global and macro-level variables that exert significant influence. Thus, "consultants need an understanding of the workplace [school] not only as a technological system but also as a complex social organization" (Gallessich, 1982, p. 5). School norms, values, philosophy, and organizational climate can greatly facilitate or impede the consultative process.

An awareness of cultural, racial, ethnic, and gender issues and a sensitivity to them are important social dynamics in the consultative relationship. These various sociocultural factors, although not often discussed in the context of consultation, can exert considerable influence on the communication process, development of trust, reciprocal and mutual understanding, and overall relationship development. In addition, they have been found to affect help-seeking patterns and utilization of services, attitudes toward self-disclosure, duration of treatment, and outcome of treatment (Gibbs, 1985; Lorion, 1978). Further, the power-authority dimension of consultation can be affected by these issues, especially when one participant is a member of a minority and the other belongs to a majority group.

Assumptions. In addition to the above competencies, several assumptions underlie consultation. First is a belief that most parents, teachers, and other school personnel usually want to be involved in the problem-solving process. We recognize that there is a subset of people who (a) wish to be told what to do rather than jointly develop interventions; (b) do not want to deal personally with the presenting problem for some reason, but rather desire and expect someone else to do it (e.g., want a child placed in another classroom); (c) fail or refuse to recognize the existence of a problem situation and thus do not seek consultative assistance; (d) do not have the skills or interests necessary to implement various interventions; or (e) face organizational restraints that prohibit or minimize their participation in the process. In addition to these groups, there are potential consultees who expect the consultant to "tell them what to do" based on their previous experiences with helping professionals, when in fact they actually would like to be involved in the problem-solving process (Zins & Curtis, 1981). This group can best be dealt with through an educative process about consultation.

A second assumption is that prevention and early intervention are advantageous for most children. There is a growing, convincing body of literature that supports this assumption (e.g., Price, Cowen, Lorion, & Ramos-McKay, 1988), although there remains a clear need for additional research regarding the preventive aspects of consultation. Third, as noted earlier, vast intervention technology exists that can be applied to address the problems experienced by children. The challenge is how to apply it within the constraints of the school setting.

Finally, all school psychological services to children and schools are best provided through a consultative framework. That is, virtually all requests for assistance in dealing with a problem should begin with consultation. Thus, services such as psychoeducational assessment and counseling are viewed as components of problem clarification or as interventions developed to solve the problem.

BEST PRACTICES

Consultative Problem-solving Process

Problem solving is the essence of consultation. It includes a number of steps: relationship development, initial designation of the problem, development and implementation of an intervention plan, evaluation of goal attainment and plan effectiveness, and planning for generalization, maintenance, and follow-up (Bergan & Kratochwill, 1990). As indicated in the following pages, it is necessary to engage in multiple levels of problem analysis and intervention development during this process. Because consultation is an indirect service, it requires that changes be brought about on more than just the individual student level. Child-related difficulties often result, at least in part, from ineffective instructional or classroom management strategies or from other causes external to the child. Consequently, it is essential to remain aware of the link between changes in the environment or in consultees' behavior and changes in the target student(s) (Hawryluk & Smallwood, 1986). In addition, it is often necessary for consultative interventions to occur at several organizational levels.

An ecological/systems perspective provides participants with a framework for developing a broad conceptualization of problems and for examining the wide range of factors that could be contributing to a problem, enabling them to avoid developing simplistic explanations for problems. As stated above, problem analysis includes a thorough assessment of consultee variables as well as other factors affecting student behavior. For example, inaccurate perceptions or expectations of a child's behavior by the consultee may contribute to a problem. Research in the area of attributions has shown that teachers generally perceive problems to be caused by factors internal to a child or due to home variables (Medway, 1979). Although child or home issues may contribute to a problem, they should not automatically be considered the only cause. Student-related problems usually result from complex reciprocal interactions between the child's behavior and the environmental and/or instructional conditions that regularly exist in a particular classroom, school, or community. Therefore, as the participants in the consultation process define and analyze problems, information should be gathered not only about the child and the immediate contingencies affecting his or her behavior, but also about the ecology of the classroom, school, and community, or the home environment itself. Obtaining a broader perspective of the problem and reconceptualizing important variables as being within teachers' or parents' power to change will impact on their causal attributions and expectations for problem resolution, as well as on the types of intervention strategies considered.

Establishing a cooperative partnership. The overall consultation process begins with establishment of a cooperative partnership (Table 1). Relationship building is a critical element of the process, beginning with the consultant's initial entry into the school and continuing throughout the proceedings. When a consultant and consultee meet for the first time, each participant attempts to become better acquainted with the other, both strive to create an atmosphere of mutual respect and trust, and together they develop a "working contract" — a basic understanding of what will occur during consultation. The contract minimally specifies the roles and responsibilities of each party, expected activities, and anticipated timeline for the consultation.

Two points in the process require clarification. First, although the steps in the problem-solving process are presented separately in this chapter, they usually overlap and thus may not occur in the exact sequence described here. Also, because of space limitations, examples in this chapter primarily refer to one-to-one consultations occurring between a school psychologist and a teacher, but they are clearly applicable to a wide range of situations (e.g., group and organizational consultations).

Clarifying the problem. The second step is to clearly define the presenting problem(s) in clear, concise, complete, and measurable terms. Because there is a level of interdependence that exists between the problem definition and the proposed intervention (Gutkin & Curtis, 1990), the following objectives need to be considered during this phase. First, consultants should help consultees describe concerns, goals, and expectations in a behaviorally specific manner. Consultees often do not have clear conceptualizations of problems when they request assistance, and they consequently present information in vague, global terms. Through skillful questioning, paraphrasing, and summarizing, a broad array of variables associated with a problem can be brought to their attention and then defined in measurable terms (see guidelines in Table 2). The collection of baseline data is an essential component of this step. Often it is expedient to divide a complex problem into its component parts, thereby helping to ensure that neither participant is overwhelmed, and that both can work toward a useful problem analysis.

At times, more than one problem may be designated, in which case they must be prioritized according to the perceived level of concern. With respect to an individual student, target behaviors can be ranked as (a) behaviors considered to be physically dangerous to self or others; (b) positive low-frequency behaviors in need of strengthening; (c) behaviors that can be naturally reinforced in the environment; (d) behaviors viewed as essential for development; and (e) behaviors that maximize functioning in a variety of settings. Further, all target behaviors selected should be consistent with developmental norms (see Kratochwill, 1985, for an excellent summary of issues in target selection). Although target behaviors are often some aspect of the child's behavior or performance, this does not imply that the child should be the only focus of the intervention. Consultees' perceptions or environmental and instructional variables are often what is changed. For example, use of teacher praise and feedback, or opportunities for students to respond in the classroom, may be altered. However, the effects of these changes are still measured in terms of student outcomes.

Questions may be raised during the problem identification (i.e., initial) interview that need to be answered by additional methods of assessment. Direct classroom observations, utilization of curriculum-based probes, analysis of student permanent products, or assessment of organizational communication or structure are among the procedures that may be considered to help answer these questions (Zins, Curtis, Graden, & Ponti, 1988).

Target behaviors must be defined in concise, measurable terms. Consultants and consultees should agree on the definition, and it should be worded in such a way that both parties (and others) can reliably record its occurrence. For instance, if lack of motivation is identified as a problem, it could be operationally defined in terms of "number of spelling assignments completed on time each day in school, and percent of correct responses." This defin-

TABLE 2
Guidelines for Behaviorally Oriented Problem Identification Interview

1. **Define the Problem.**

   Clarify vague general statements regarding the consultee's concerns. ("You say that Rob is aggressive toward other children. Can you give me some specific examples of his aggressive behavior?")

   Develop an operational definition of the problem. Define the problem in measurable terms. Make it specific enough that others will be able to recognize it when they see it.

   Collect information about the frequency and duration of the problem. ("How many times per day does Mary shout out in class? How long does each episode of behavior last and for what length of time has the problem been occurring?") Baseline data should be collected.

   Assess intensity or severity of behavior. ("Describe what types of things Brian does when he throws a temper tantrum.")

   If more than one problem is presented, prioritize and select one target behavior on which to work initially.

2. **Identify Antecedent Determinants of the Problem Behavior.**

   Identify temporal and situational antecedents. ("Are there times of the day when the behavior occurs most frequently? In which settings does the behavior occur?")

   Identify the behavior of others that may trigger or maintain the behavior. ("It seems that whenever you are paying attention to other children, John's disruptive behavior intensifies.")

   Identify and analyze conditions that alleviate the problem. ("Does Sue seem to work better when you have structured her independent seatwork time through the use of goal setting and a timer?")

3. **Identify Consequences That May Maintain the Behavior.**

   Explore positive consequences that currently are provided or could be instituted to improve behavior or performance. ("What do you do when Joe completes all of his homework?" "What things does Cindy really like to do?")

   Explore forms of inappropriate reinforcement or attention operating.

4. **Assess Other Relevant Environmental Variables.**

   Identify significant others in the child's environment and assess their attitudes, attributions, and expectations regarding the problem and the child in general.

   Assess the discrepancy between the child's behavior and expected behavior. ("Howard is out of his seat on an average of 15 times per half hour period. How many times would it be acceptable for him to be out of his seat within this time period in your classroom?")

   Assess relevant instructional variables and classroom or home routines.

5. **Identify All Available Resources.**

   Identify the strengths of the child. ("What types of things does Lisa do well?" "In what subject areas is William succeeding?")

   Identify materials and human resources available for intervention (e.g., peer tutors, parent volunteers, special instructional materials).

Note. Adapted from Peterson (1968).

ition is specific, easily measurable, and understandable to all.

Problem analysis. Once the target behaviors have been identified, a comprehensive functional analysis of the interaction that exists between the child's behavior and the environment is conducted (see Gresham, 1991). The baseline data and results of the assessment procedures are key components of this step, as they provide a first-hand look at the complex interactions that occur between students, consultees, and their daily environments. Temporal and situational antecedents that appear to contribute to the problematic behavior should be identified. In addition, situations in which the behavior of concern does not occur can be noted, and consequences operating to maintain the behavior can be recorded. When identifying consequences, consultants should obtain information on (a) appropriate positive reinforcement that is given, (b) forms of inappropriate reinforcement or attention gained by exhibiting the behavior, (c) the schedules of reinforcement in operation, and (d) reinforcement histories.

Relevant environmental and instructional variables that operate regularly within a child's classroom or the larger context must also be identified and analyzed. For instance, a consultant could determine whether the teacher had developed a set of rules to establish consequences for particular behaviors, how consistently the rules are enforced, amount of reinforcement available to the child from sources other than the teacher, peer reactions to the target behavior, opportunities the student is given to respond (both oral and written), method and delay in providing instructional and behavioral feedback, and appropriateness of curriculum (Witt & Martens, 1988). For academic problems, a task analysis of student skills in a particular subject may be necessary through methods such as curriculum-based assessment/measurement, examination of permanent products, and think-aloud techniques. Teacher and/or parent perceptions and expectations also should be explored to help them understand the broad array of factors that could be influencing the child's behavior or performance. As a result, they must be more open to making needed changes in behavior management or instructional strategies. Finally, other variables such as peer interactions and school norms should be examined.

Instructional practices of teachers and daily classroom, school, and home routines also need to be clarified to obtain a broad ecological perspective. Many problems that appear to be individually based are not; on closer examination it may be seen that they require systems-level intervention. Traditionally, however, not much attention has been given to the environments of children and the adults who function in their environments. Nevertheless, it is the adults, not the child, who primarily control the environment in which a child functions (Saxe, Cross, & Silverman, 1988). In addition, teachers may require help in operationalizing what is acceptable behavior or performance in the classroom so that reasonable goals for the child can be developed.

Finally, all resources that potentially can be utilized in the development and implementation of interventions must be identified. These include student strengths, aspects of the system that are helping the child be successful in other situations, and material and human resources (teacher, time, parents, peer and volunteer tutors, community support systems) available for intervention.

Brainstorming and exploring intervention options. Once the problem is clearly defined and analyzed, the level of intervention must be determined. For example, a program could be developed for an individual student, the focus could be on helping a teacher change instructional practices or behavior management strategies used for an entire class, the district's reading curriculum could be altered, or its policy on corporal punishment could be modified. When participants agree on the level of intervention, they then generate as many treatment options as possible. The cardinal rule of this phase is to avoid evaluating ideas until the brainstorming process is completed. There often is more than one way to resolve a problem, and by generating a number of possible solutions, the probability is maximized of identifying an intervention that will be both effective and acceptable to the consultee.

Interventions usually consist of some form of environmental manipulation because (a) there is substantial research specifying what types of environments lead to effective teaching, parenting, and behavioral change; (b) all consultees routinely manipulate meaningful school and home environmental variables; and (c) most consultees do not have the skills to engage in nonenvironmental manipulations such as counseling. Examples of variables that can be considered for manipulation include reinforcement and punishment contingencies, curriculum content, instructional techniques, teacher behavior, peer and sibling behavior, physical arrangement of the home and classroom, and the school administration (Gutkin & Curtis, 1990).

Selecting an intervention. After a number of intervention ideas have been generated, each should be evaluated to determine potential benefits and risks for the child, unintended side effects, and feasibility of implementation. There generally are no "packaged" solutions to problems. A taxonomy of interventions related to a corresponding taxonomy of diagnoses does not exist (Gutkin & Curtis, 1990); therefore, treatments selected during consultation are simply high-probability hypotheses. After a careful analysis of the problem is conducted, hypotheses are formulated regarding what is eliciting and maintaining the behavior or situation, and intervention strategies are developed from this information. Although the consultant guides this problem-solving process and maintains primary responsibility for providing adequate information about the various intervention procedures identified, both contribute to the process and the ultimate selection of strategies rests with the consultee. The following guidelines are useful in generating and selecting interventions.

1. Implement positive intervention approaches before resorting to behavior suppression or reduction techniques in all but extreme cases.

2. Choose the least complex and least intrusive intervention possible. To the extent possible and appropriate, the focus should be on helping consultees to modify instructional variables or general behavior management strategies. Alterations in existing techniques usually are less intrusive or aversive to teachers than is learning a new procedure.

3. When a new skill must be developed by the consultee, design it to fit into the present structure and routines as much as possible.

4. Develop a pool of resources, such as peer and volunteer tutors or community resources, that can be utilized when changes in the classroom are not possible or not sufficient to resolve the presenting problem.

5. Provide support and reinforcement to consultees for implementing the intervention. Because a behavior change on consultees' part is often required, consultant support will encourage their continued enthusiasm and adherence in treatment implementation.

6. Promote interventions that require less time, are ecologically unintrusive, and are perceived by consultees to be effective. These types of interventions tend to be more acceptable to consultees (Elliott, 1988).

7. Finally, focus intervention efforts on promoting change at the highest organizational level possible.

Clarifying implementation procedures and responsibilities. Just as the nature of consultation was clarified in the initial meeting, the pragmatic aspects of implementation should be clarified once the intervention is selected. First, the roles and responsibilities of all participants with regard to the intervention must be delineated and agreed upon. The specific techniques should be outlined in a step-by-step fashion and potential reinforcers identified (often through a formal reinforcer assessment). The time(s) of the day and the settings or subject areas in which the intervention will be implemented must be decided. At this point, consideration should be given to programming for generalization. Specific suggestions for maximizing the probability that behavior change will generalize across time, persons, and settings are provided later in the chapter. All aspects of the plan should be put in writing at least in outline form (often in a written protocol format), so each person involved has a clear idea of her or his responsibilities. This written plan also serves as a record for accountability purposes.

Implementing the strategy. Once the intervention plan is developed, consultants should keep in close contact with consultees to aid in implementation, provide technical assistance, and reinforce consultees' efforts. Consultees often have questions about the details of the plan, unanticipated behaviors may arise, or there may be unintended reactions from other children. Consultants can enhance consultees' motivation by involving them in goal setting, establishing a trusting and warm relationship, and demonstrating personal competence (Brown & Schulte, 1987). Further, if an intervention requires the consultee to learn a new skill or to make substantial changes in current practices, it often is helpful for the consultant to model the procedure, observe the consultee implementing it, and provide constructive, supportive feedback. All of these elements — ongoing contact, adequate training, and support — are crucial for increasing and ensuring treatment integrity and success.

Consultees' resistance to a planned intervention may occur, although it can be minimized through establishment of a cooperative, supportive partnership. However, consultants must remember that the consultation process may (a) require considerable consultee effort and time, (b) focus on consultee failure, (c) involve differing perspectives of desirable outcomes, and (d) not result in immediate problem resolution (Piersel & Gutkin, 1983). Because each of these possibilities is nonreinforcing for consultees, at least on a short term basis, it is understandable that resistance is often encountered. By being aware of the potentially negative aspects of consultation, consultants may be better prepared to deal with any resistance. Further, there are many legitimate problems that consultees face that may prevent them from being able to carry out interventions as planned.

Evaluating intervention effectiveness and follow-up. There are several interrelated aspects of this stage of the problem-solving process, including evaluation of intervention effectiveness, generalization, fading, and follow-up.

Evaluation of intervention effectiveness. Once the intervention plan is implemented, it should be systematically and regularly monitored to ensure treatment integrity and to identify any unintended side effects. Of course, the evaluation plan should be agreed upon before intervention implementation begins. Generally, the same data collection procedures used to obtain baseline information can be applied again as a means of evaluation. These methods should be as simple and time-efficient as possible, so that a teacher, student, parent, or peer can easily use the system. Single-subject methodologies such as single phase, reversal, or multiple baseline designs are often used to evaluate intervention effectiveness. These evaluation procedures may suggest that (a) the intervention resulted in attainment of desired goals, thereby indicating that follow-up monitoring and/or generalization and fading procedures are needed, or (b) the intended outcomes were not reached entirely, suggesting the need to recycle through earlier problem-solving steps.

Generalization, facing, and follow-up. Evaluation data will indicate the degree to which the intervention is producing the desired outcome. Once an effective and reliable procedure has been identified, the intervention can be extended to other settings or systematically faded.

Although there are many well-developed, validated techniques for bringing about behavior changes, we know substantially less about how to maintain these gains. A number of suggestions, however, have been offered in the literature on how to program generalization as interventions are developed and as they are implemented (Meichenbaum & Turk, 1987). Selected reinforcers, for instance, should be naturally occurring events when possible, and techniques should be implemented that lend themselves to fading or to greater transfer of control to the student (i.e., self-management approaches). Students should take an active role in intervention development when possible, and efforts should be made to help them understand the usefulness and relevance of the intervention to their lives. Training should take place in a number of settings and should involve multiple tasks and trainers. Finally, opportunities to confront and deal positively with failure or mistakes also should be built into the intervention procedures.

Interventions that include specific prompts or reinforcement contingencies need to be faded systematically once the child is performing at desired levels. It is important to withdraw prompts or reinforcements in small steps rather than all at once to ensure maintenance of treatment gains. Fading can consist of increasing the amount of time before a child can earn a reinforcer, increasing task demands to earn a reinforcer, or decreasing the number of prompts given to children to elicit performance. If at any step in the fading process the student's behavior begins to deteriorate, reinforcement or prompting should revert to the previous level. Once the child's behavior stabilizes again for a period of time, fading can be continued.

The importance of follow-up by consultants during this stage is critical, although it is often neglected. Follow-up helps ensure that intervention procedures are being implemented correctly, and it can address the issue of unintended outcomes. When interventions provide ineffective or unreliable outcomes, consultants should observe them in operation and conduct a functional analysis of the current situation to determine what conditions might be contributing to the nonattainment of the desired goals. Oftentimes, modifications in the existing plan that are suggested through corrective feedback are all that is necessary to increase ease of implementation, improve intervention effectiveness, or counteract unanticipated student responses. If the alterations do not result in better outcomes, a new strategy should be sought, once again through the problem-solving process.

Influences on the Consultation Process

Central to the success of the consultation process are the issues of treatment acceptability, adherence, and integrity. Consideration of these issues, and the establishment of a cooperative partnership can be major factors in decreasing or avoiding resistance. Acceptability refers to judgments or beliefs of consultees and students about whether a treatment is "appropriate, fair, and reasonable for the problem or client" (Kazdin, 1981, p. 493). As Wolfe (1978) notes, if participants like the intervention (i.e., find it acceptable), they may be more likely to use it or to carry it out correctly. Adherence involves the willingness of (a) the consultee to carry out the intervention to its completion, and (b) the student to engage in certain behavior changes indicated in the intervention plan (Meichenbaum & Turk, 1987). Treatment integrity, on the other hand, refers to the extent to which the consultee implements the intervention plan as intended (Gresham, 1989). Elliott (1988) proposes that the elements of acceptability, adherence, and integrity are reciprocally dependent, that is, they influence and are influenced by one another. Adherence and integrity are the two elements that link intervention use with effectiveness.

Because consultation is an indirect service and interventions are almost always implemented by consultees, there are two levels of acceptability and adherence related to the process. The first involves the extent to which the consultee is actively involved in carrying out a mutually acceptable course of action to produce a desired behavior change in a child. The second level involves the extent to which the child is involved in the process and cooperates with the treatment plan implemented by the consultee (Meichenbaum & Turk, 1987). Further, there are certain factors related to treatment integrity that affect implementation, including the complexity of the intervention, time required to implement the plan, materials or resources needed, number of treatment agents involved, perceived and actual effectiveness of the intervention, and motivation of the consultees (Gresham, 1989).

When interventions are not followed or result in failure, consultants most often cite consultee variables such as motivation or skill as the cause (Martin & Curtis, 1981). Although consultee motivation may play a role in the success or failure of consultation outcome in some cases, it is not the predominant variable, nor is it within the consultant's sphere of control. As indicated in Table 3, there are numerous factors that influence both adherence and treatment integrity. Although correlational in nature, these factors can provide useful guidelines for consultants interested in enhancing both adherence and treatment integrity on both the consultee and the student levels. It is evident from the literature, for instance, that relationship variables are of crucial importance. Adherence can be improved and resistance decreased through the establishment of a supportive, cooperative partnership characterized by open communication. As mentioned previously, efforts should be made early in the process to clarify consultee beliefs and expectations about the consultation process and about intervention options and outcomes. In addition, discrepancies between consultant and consultee

TABLE 3
Examples of Factors Affecting Treatment Adherence and Integrity

- Client (Student) Variables
  - Belief that a problem exists
  - Belief that the problem could have a negative impact on the student
  - Belief that participating in the intervention will help the student
  - Perceptions regarding not having a choice about being treated
- Consultee Variables
  - Beliefs about potential efficacy of the intervention
  - Understanding of the consultative process
  - Satisfaction with the relationship with the consultant
  - Misconceptions held
  - Cultural beliefs and values
  - Opportunities available to exhibit skills
  - Beliefs about ability to carry out the intervention
  - Personal motivation to resolve the problem
  - Skills in describing problem situations and carrying out interventions
  - Perceptions of consultant's expertise and competence
- Consultant Variables
  - Theoretical orientation and values
  - Skills in problem solving
  - Technical competence in intervention development and evaluation
  - Understanding of organizational functioning and change
  - Motivation and enthusiasm
  - Self-awareness and understanding
- Relationship Variables
  - Interpersonal and communication factors
  - Discrepancies between consultant and consultee attributions
  - Participant sensitivity to cultural, racial, ethnic, and gender issues
  - Extent of cooperation or mutual participation in process
  - Continuity of involvement
  - Extent of support and follow-up provided
- Treatment Variables
  - Complexity of the intervention
  - Time and resources required to carry out the interventions
  - Intrusiveness of intervention relative to established regularities
  - Duration of intervention
  - Number of behavior changes that are made at once
  - Number of treatment agents involved
  - How soon behavior chnage is observed
- Organizational Variables
  - Openness of social/organizatioal climate
  - Opportunities and support provided for change
  - Length of time until assistance is provided
  - Perception of organizational support
  - Time and resource availability
  - Principal's leadership behavior

Note. Adapted from Gresham (1989), Gutkin (1986), and Meichenbaum and Turk (1987).

causal attributions for the problem need to be resolved during problem clarification (Zins, 1985).

Other factors that affect treatment adherence include characteristics of the intervention procedures chosen and the extent to which the client is involved in the process. A related issue is that of consultant adherence (Meichenbaum & Turk, 1987). Consultants need to be aware of their own beliefs regarding their ability to improve consultee and client adherence, make efforts to monitor their own interactions with consultees, and develop the type of consultative relationship that maximizes the probability of adherence. Finally, because consultation often results in short-term negative outcomes for consultees, as noted earlier, the importance of providing support and encouragement is underscored.

Organizational Consultation

School consultation is not limited to one-to-one interactions between a consultant and a consultee, or to behavioral change in individual students (although those are the foci of this chapter). At times consultation is expanded to include groups of consultees (as discussed below), an entire school, or even a school district. Consultants increasingly are focusing on larger organizational issues to expand and maximize their influence, and to deal with problems that truly are systemic in origin. The same problem-solving procedures described above are followed in these instances, but of course there is a different focus and other types of interventions are developed. However, behavior-analytic and social-learning procedures continue to be relevant. Examples of organizational consultation include involvement in the evaluation of a districtwide program for gifted students, establishment of a smoking prevention program in a middle school, development of a program for senior high students to encourage safety belt use and avoidance of alcohol, implementation of a tutoring program that utilizes the services of volunteer senior citizens, and initiation of a health promotion program for school employees. There continues to be a need to develop new approaches that will expand opportunities to intervene to help students, and broad, systems-level approaches are essential in this respect.

Emerging Areas of Practice

Consultation practice in schools continues to grow and evolve rapidly. Below are four issues we believe will become more prominent in the future.

Group consultation. The "spread of effect" nature of consultation holds that a consultant, by working directly with a single consultee, can potentially affect the lives of numerous children (Gutkin & Curtis, 1990). Extending this approach, one can see the multiplicative impact of a consultant who sees many consultees over time. Taken one step further, if a consultant meets simultaneously with many consultees by using a group format, consultation's spread of effect may be maximized. Group consultation thus could be an efficient and cost-effective way of conducting school consultation. Also, to the extent the consultant is able to harness supportive elements of the group process, to keep a task focus, and to structure and organize the group, consultation outcomes may be more favorable than those resulting from a one-on-one approach (Wilcox, 1980).

Group consultation has rarely been discussed in the school psychology literature. However, given continuing and mounting demands on school psychologists' time, we believe greater attention should be, and will be, directed toward research and practice issues concerning school group consultation, perhaps in the context of intervention assistance programs.

Consultation vs. collaboration. When the consultant and consultee work in the same setting, many of the fundamental assumptions on which consultation is based are impractical or may prove difficult to follow. These assumptions include voluntary consultee participation (Harris & Cancelli, 1991), confidentiality of communications, complete consultee freedom to accept or reject advice, and lack of consultant responsibility for student outcome (Caplan & Caplan, 1993). In addition, school psychologists' frequently enhanced status (e.g., advanced degree, salary level) relative to that of consultees works against achieving equal relationships.

Given these circumstances, it may be advisable to reexamine aspects of the traditional consulting role of the school psychologist. As one alternative, Caplan and Caplan (1993) have proposed a model of mental health collaboration for internal consultants such as school psychologists. The primary differences between mental health consultation and mental health collaboration are that in collaboration (a) the school psychologist shares equal responsibility with the consultee for the overall outcome for the student, but primary responsibility for the mental health outcome; and (b) the consultee does not have the freedom to accept or reject advice, because the best possible course of action must be selected and implemented to improve the student's condition. Mental health collaboration involves not only direct intervention with the student by the school psychologist, but also efforts to educate and influence other school personnel with respect to the mental health aspects of their role in the case (Caplan & Caplan, 1993).

The potential utility of mental health collaboration is considerable, as collaboration has been consistently preferred over more indirect service approaches in studies of school personnel's service delivery preferences (Babcock & Pryzwansky, 1983). A collaborative approach, defined as consultation with an added direct service component, also has been shown to produce (a) favorable teacher perceptions regarding the effectiveness of consultation services, and (b) better academic outcomes for students with learning disabilities relative to pull-out programs (Schulte, Osborne, & McKinney, 1990).

Caplan (1993) proposes that collaboration ultimately should replace consultation as the preferred mode of interprofessional communication used by school psychologists. Whether this will occur will remain a matter of speculation for some time. However, based on early empirical evidence and the corresponding interest among other special services professionals (e.g., Morsink, Thomas, & Correa, 1991), there is good reason to explore the practice of mental health collaboration in school psychology.

Collegial support. Intervention assistance programs, which emphasize the development of interventions through consultation before a referral is made for special education assessment, are now recommended or mandated educational services in at least 70% of the states (Carter & Sugai, 1989). Descriptions of these programs typically include consultation involving a regular educator and a special services professional, and/or a team of special services staff (Zins, Curtis et al., 1988). Recently, however, there has been increased recognition of the importance of the consultative problem solving that occurs between regular educators, and suggestions to formally include such procedures (i.e., collegial support) as a component of intervention assistance programs have been made (Zins & Johnson, 1994). The fact is, such interactions between teachers have always occurred, even though the teachers may not have received preservice training in such skills and these activities are not encouraged by the structure of most school organizations. Rather, teachers traditionally have been accustomed to functioning in a somewhat isolated manner from their peers (Lieberman & Miller, 1984), and they have little time for reflecting on alternative means of meeting the diverse needs of their students. However, as there is increasing recognition of the need for teachers to engage in problem solving and reflection, and as the occurrence of collegial interactions among regular education teachers is increasing, school psychologists should support and encourage these efforts and view them as a component of the overall consultative approach to educational services. There are indications that the efficacy of the consultation process increases as teachers are trained in it (Anderson, Kratochwill, & Bergan, 1986).

Professional self-management and support. School psychologists often are the only mental health professionals in a school. Consequently, they may find themselves isolated from others with similar professional interests who deal with like problems on a daily basis. In addition, school psychologists are members of a profession that is rapidly changing and are faced with an explosion of new knowledge and techniques. For these reasons, it is becoming increasingly important for them to proactively manage their professional skill development (and thus their roles) and to have available the support of other school psychologists. To meet these challenges, many have joined peer support groups. Participation in peer support groups enables them to learn from one another, to support one another, and to jointly solve problems (Zins, Maher, Murphy, & Wess, 1988). Thus, consultation with school psychology colleagues can play an important part in maintaining one's professional expertise and in addressing real-life problem situations.

SUMMARY

As consultation continues to become a major aspect of many school psychologists' jobs, it is critical for them to keep abreast of the latest theoretical and empirical knowledge of this emerging field. The knowledge base of effective consultative interactions, systems-level influences, and evaluation techniques is quickly expanding, and this chapter represents an integrative summary of many of the most important of these recent developments. Included was a review of the essential aspects of consultation practice, including its emphasis on a cooperative partnership, a preventive and empowering ideology, consideration of systems issues and of the reciprocal and interdependent nature of the interactions, and a review of the most important dimensions of the problem-solving process. It concluded with a forecast of issues considered to be significant to the development of the future practice of school consultation. Our intent was to succinctly review the essential information needed to effectively engage in consultation. Ultimately, it is hoped that improvements in consultation practice will result in school psychologists being identified with consultation-based services rather than with traditional IQ testing, so that successful outcomes for children occur with increasingly frequency.

ACKNOWLEDGMENTS

We would like to gratefully acknowledge the many contributions of Charlene R. Ponti, who was coauthor of the previous version of this chapter. In addition, we benefited from the helpful feedback of Jan N. Hughes on an earlier draft of the chapter.

ANNOTATED BIBLIOGRAPHY

Brown, D., Pryzwansky, W. B., & Schulte, A. C. (1991). *Psychological consultation: Introduction to theory and practice* (2nd ed.). Boston: Allyn & Bacon.
A very useful source for those who seek to develop the essential knowledge and skills of consulting, this text examines various models of practice and presents in detail the stages and processes of consultation. The chapters that concern consulting with teachers and parents seem especially germane to the practice of school psychology.

Caplan, G., & Caplan, R. B. (1993). *Mental health consultation and collaboration*. San Francisco: Jossey-Bass.
This book is a revision of Gerald Caplan's (1970) seminal work, *The Theory and Practice of Mental Health Consultation*, one of the most frequently cited books in school psychology. Besides updating the mental health consultation model, the Caplans describe mental health collaboration. They argue that internal consultants such as school psychologists should use collaboration rather than consultation.

Gutkin, T. B., & Curtis, M. J. (1990). School-based consultation: Theory, techniques, and research. In T. B. Gutkin & C. R. Reynolds (Eds.), *The handbook of school psychology* (2nd ed., pp. 577–611). New York: Wiley.
This well-referenced chapter provides a comprehensive overview of key issues associated with consultation in the field of school psychology. The authors' coverage of the rationale for consultation, major approaches to school consultation, and critical presentation of contemporary and future issues are particularly noteworthy.

Erchul, W. P. (Ed.). (1993). *Consultation in community, school, and organizational practice: Gerald Caplan's contributions to professional psychology*. Washington, DC: Taylor & Francis.
Contributors to this edited book describe and evaluate Caplan's innovative approach to consultation and related activities with respect to current and future practice of school, community, and organizational psychology. Caplan himself authors two chapters in this volume, which offers an intriguing historical perspective on the development of community mental health and school-based consultation.

Zins, J. E., Kratochwill, T. R., & Elliott, S. N. (Eds.). (1993). *Handbook of consultation services for children: Applications in educational and clinical settings*. San Francisco: Jossey-Bass.
Following the editors' overview of the history and current status of consultation, chapter authors review conceptual foundations, models, processes, evaluation considerations, practice issues, and training approaches pertaining to the field. The book is the most complete source of information for the school-based practitioner or researcher, and also contains extensive references that readers may consult for additional information.

Best Practices in Evaluating the Effectiveness of Applied Interventions

Mark W. Steege
University of Southern Maine

David P. Wacker
The University of Iowa

OVERVIEW

School psychologists, along with members of educational teams, share a critical responsibility for monitoring the effectiveness of interventions. There are three advantages to evaluating the effectiveness of interventions. First, the more precise and thorough we are in our evaluation procedures, the more information we will obtain about students. Second, by evaluating interventions across target behaviors, students, teachers, parents, and settings, the school psychologist will identify a wide repertoire of potentially useful interventions. Finally, ongoing monitoring of students' performance during the delivery of an intervention allows the school psychologist to identify specific procedural difficulties and to make necessary modifications to intervention components, thereby increasing the effectiveness of the intervention package.

The evaluation of the effectiveness of an intervention is a formidable task, but one that is frequently underestimated. At the most basic level, evaluating the effectiveness of an intervention involves answering a yes/no question: Did the student improve with intervention? Put in slightly more operational terms: Following intervention, did the behaviors targeted for intervention change in the desired direction? This type of question is really a two-part question that involves both an *outcome* and a *causal* relationship. Fairchild and Zins (1992) discussed the importance of outcome data as documentation of accountability, and as a measure of student progress, and of the performance of school psychologists. Outcome data provide information about behavior change (e.g., decrease in self-injury, increase in students' completion of homework, increase in prosocial behavior of students, increase in reading comprehension) as a direct result of interventions orchestrated by the school psychologist. In short, outcome data document behavior change, and indirectly document the performance of professional(s) responsible for the planning and implementation of the intervention. However, documentation of students' improvement is not sufficient. A best practices model must also demonstrate a causal relationship between the intervention and outcomes, a relationship in which the intervention (independent variable) is responsible for any change in outcome (dependent variable).

A causal relationship between an intervention and behavior change is determined through validating that the outcomes are attributable solely to the intervention and not to extraneous and/or confounding variables. While outcome data are derived by measuring students' behavior, causal relationships are validated through the use of specific methodology.

The best practices method of collecting outcome data is by direct and reliable measurement of students' behavior. Direct measurement of behavior enables the school psychologist to document significant, meaningful, and socially valid outcomes. The best practices method of determining a causal relationship between an intervention and an outcome is through the use of single-case experimental designs. Single-case experimental designs enable the school psychologist to conclude with a high degree of certainty that the intervention was responsible for a student's behavior change (Rush, Rose, & Greenwood, 1988). An evaluation methodology that involves direct, reliable measurement of student behavior, and single-case experimental designs that control for confounding variables, results in data that document both outcome and causation.

The following sections will discuss several issues that are of critical importance to the measurement of intervention outcomes and to the validation of the causal relationship between the intervention and outcomes. Methods of defining and measuring behaviors, and of using single-case experimental designs, to evaluate the effectiveness of interventions will be emphasized.

TABLE 1
Examples of Ambiguous and of Operationalized Definitions

Example 1:

Ambiguous definition — Appropriate hand raising.

Operationalized definition — Matthew raises his hand and, when called on to respond by the classroom teacher, verbally contributes to class discussion.

Example 2:

Ambiguous definition — Self-injurious behavior.

Operationalized definition — Self injurious behavior, such as Daniel's putting his hand or wrist to his mouth with his teeth contacting the skin.

BASIC CONSIDERATIONS

Defining and Measuring Behaviors

To evaluate the effectiveness of an intervention, the school psychologist needs to first develop clear, unambiguous, and concise definitions of specific behaviors upon which the intervention is intended to impact. Specifically, this means that after reviewing a written description of a target behavior, two observers would be able to observe a student and agree that the target behavior occurred. Behaviors are *operationalized* when they are clearly described. Operationalized definitions of student behavior allow for a reliable measurement of outcomes. The examples in Table 1 illustrate operationalized and ambiguous target behaviors.

Direct Observation

The most frequently used method of measuring behavior is direct observation. There are several methods of direct observation including event recording, duration recording, *and interval recording*. Each of these procedures has advantages and disadvantages. The selection of a measurement procedure is driven by the topography, frequency, and duration of the target behaviors. Therefore, it is recommended that, prior to deciding on an observation system, the school psychologist conduct a brief anecdotal observation to identify behavioral characteristics, setting events, and so forth, and select a method of observation that will yield the most reliable and valid data.

Event recording, or frequency recording, involves the tallying of discrete occurrences of the target behavior. Event recording is most applicable to recording behaviors that are discrete episodes or responses. For example, event recording could be used to measure the number of times a student raised her hand before contributing to class discussion, and the number of times she contributed to class discussion without raising her hand. Figure 1 illustrates the use of an event recording procedure to measure the frequency of handraising and of inappropriate verbalizations for one student in three classroom settings. These target behaviors were identified and defined during an interview with the classroom teacher prior to the intervention.

The school psychologist observed and recorded eight occurrences of appropriate handraising and 17 occurrences of inappropriate verbalizations across the three classroom settings. On the basis of these data and additional behavioral assessments, the school psychologist could collaborate with the classroom teacher in the design and implementation of an intervention to increase appropriate handraising and decrease inappropriate verbalizations in the classroom.

The disadvantages of event recording include the fragmentary view it gives of the stream of behavior, and the potential unreliability of observations when behavior onset and cessation are difficult to discriminate (Barlow & Hersen, 1984).

Duration recording notes the length of time that occurs between the onset of a specific behavior and the termination of the response. Duration recording is most applicable in measuring behaviors that involve persistence. For example, duration recording could be used to record the amount of time in which a student engages in social interactions (i.e., dyadic verbal exchanges) with peers. Duration recording is the least used of the measurement procedures, perhaps in part because of the apparent ease in estimation of duration by the use of interval recording procedures (Barlow & Hersen, 1984).

Interval recording involves measuring the occurrence or nonoccurrence of prespecified target behaviors during predetermined units of time. Whereas in event recording the observer records the number of times a behavior has occurred, in interval recording the observer is concerned with the number of intervals in which a behavior occurs. Because interval recording is applicable to a wide range of responses, and is particularly useful in measuring responses that

FIGURE 1. Event recording of appropriate handraising and inappropriate verbalizations.

Target Behaviors

1. Appropriate hand raising: raises hand and when calledon to respond by the classroom teacher, verbally contributes to class discussion (AHR)
2. Inappropriate verbalizations: offers verbal responses prior to raising hand and being called on by classroom teacher to participate in discussion (IV)

do not have clear distinguishable onset and termination, it is the most commonly used of the behavior measurement procedures.

There are three methods of interval recording: *partial interval, whole interval time sampling,* and *momentary time sampling.* In partial interval recording, the observer posts a response if it occurs at any time within a prespecified interval. For example, given a 10-second interval, an observer records as an occurrence of on-task behavior if the student was engaged in on-task behavior during as little as 1 second or as much as 10 seconds of the interval. With whole interval time sampling, the observer registers as an occurrence behaviors that persist throughout the *entire* interval. For example, given a 10-second interval, the observer records an occurrence of on-task behavior only if a student was engaged in on-task behavior during the entire 10 seconds. With momentary time sampling, the observer watches the student precisely at predetermined intervals, and notes whether a target behavior is occurring at the moment the observation occurs. The school psychologist could use momentary time sampling to record on-task behavior by observing the student at 1-minute intervals and recording on-task behavior if the student was actively engaged in the educational task. During a 15-minute observation session, a 10-second partial and whole interval procedure would result in continuous observation of the student's behavior and 90 recordings of the target behaviors. In contrast, a 1-minute momentary time sampling procedure would result in 15 recordings of the target behaviors. Of these three methods, partial interval recording is preferred for measurement of high-frequency, and rapidly occurring (e.g., self-injurious headbanging) behaviors. Whole interval recording is recommended when continuous occurrence of the target behavior is expected (e.g., when recording sustained attention to tasks). Momentary time sampling is useful when continuous observation of a student is not practical, or when an observer is monitoring and measuring target behaviors with several students in one setting.

It should be noted that interval recording procedures provide only estimates of rate and duration of occurrence of target behaviors. The results of observations are reported in terms of the *number of percentage of intervals* in which target behaviors occur. Of the interval recording procedures, partial interval recording is the most frequently used.

Figure 2 displays a 6-second partial interval recording procedure that was used to measure the behavior of a student who had been referred to the school psychologist for behavioral assessment of self-injurious vis-a-vis appropriate behaviors.

To carry out this procedure, during an interview with the classroom teacher and support personnel, self-injury was defined as handbiting behaviors (i.e., student placed hand in mouth with teeth in contact with the hand) and appropriate behavior was defined as task participation (i.e., the student actively engaged motorically in functional and age-appropriate task). The results of this 5-minute observation

FIGURE 2. Partial-interval recording of self-injurious and of appropriate behaviors.

Target Behaviors

1. Self-injurious handbiting behaviors (SIB)
2. Appropriate behavior (AB)

2	2	2	2	1	1	2	2	2	2	1 2
3	1	1	1	1 2	2	2	2	2	2	2
4	2	2	2	2	2	1	1	1	1	1
5	1	1	1	1	1	1	1	1	1	1

Percentage of Intervals in which Target Behaviors Occured

1. SIB = 28/50 = 56%
2. AB = 25/50 = 50%

demonstrated that self-injury occurred during 56% of the intervals and appropriate behavior occurred during 50% of the intervals. Note that during three of the intervals both self-injury and appropriate behavior occurred. This is possible in a partial interval recording procedure because the occurrence of one behavior during the interval does not preclude the occurrence of another behavior during the same interval.

Interobserver Agreement

An important consideration in measurement of student behavior is the accuracy of the recording method. Accuracy of measurement is defined in terms of *interobserver agreement*. Interobserver agreement refers to common findings by two or more observers or raters, on the occurrence and nonoccurrence of target behaviors, the ratings of behaviors, or the ratings of permanent products. There are several methods of determining the degree of interobserver agreement. The most commonly used method involves the use of the following formula:

Interobserver agreement = Number of agreements ÷ (Number of agreements + Number of disagreements) x 100

For example, suppose that using an event recording procedure to measure a student's social interactions during morning recess, two observers simultaneously and independently observed and recorded initiations of peer-directed social interactions. Observer 1 recorded 12 occurrences of the target behavior, while Observer 2 recorded 10. Interobserver agreement was calculated as follows:

Interobserver agreement = 10 ÷ 10 x 2
= 10 ÷ 12 = 83%

Generally, an interobserver agreement percentage of 80% or greater is considered the standard for concluding that the measurement of student behavior is reliable and valid. Interobserver agreement must be conducted for 25%–30% of the sessions/samples in order to document a trend. During the evaluation of the effectiveness of an intervention, the school psychologist could serve as the primary observer/rater to measure student behavior, and a trained secondary observer/rater could be enlisted to simultaneously, but independently, measure student behavior during the 25%–30% of the sessions.

BEST PRACTICES

Use of Single-Case Experimental Designs to Evaluate Interventions

Single-case designs are a powerful technique for discovering and validating effective interventions (Rush et al., 1988). Unlike group designs, which include an experimental and control group, in single-case designs, the student serves as his or her control. This means that the student's behavior is considered before, during, and following the intervention. The degree of variation in the student's behavior during these phases allows the school psychologist to determine the effectiveness of the intervention.

Single-case experimental methodology establishes a functional relationship between the independent variable (i.e., the intervention strategy: for example, a token economy program) and the dependent variable (i.e., the expected outcome; for example, an increase in prosocial behavior and a decrease in peer-directed physical aggression). Single-case experimental designs are able to control for rival explanations for changes in student behavior.

Repeated measurement of the target behavior(s) across the distinct phases of the intervention is a significant characteristic of single-case experimental designs. They are contingency-driven, meaning that the conditions within the design continue or are changed as a function of the behavior measured (Wacker, Steege, & Berg, 1988). This facilitates responsive adjustments to the intervention in order to effect positive change in target behaviors. Single-case designs begin with a baseline condition, in which no intervention is introduced. During this phase the student's behavior is measured for several sessions until a stable trend in behavior has been established. It is a mistake to discuss the length of baseline in an a priori fashion (e.g., baseline will continue for three sessions), because baseline must continue until stability in the rate of behavior occurs.

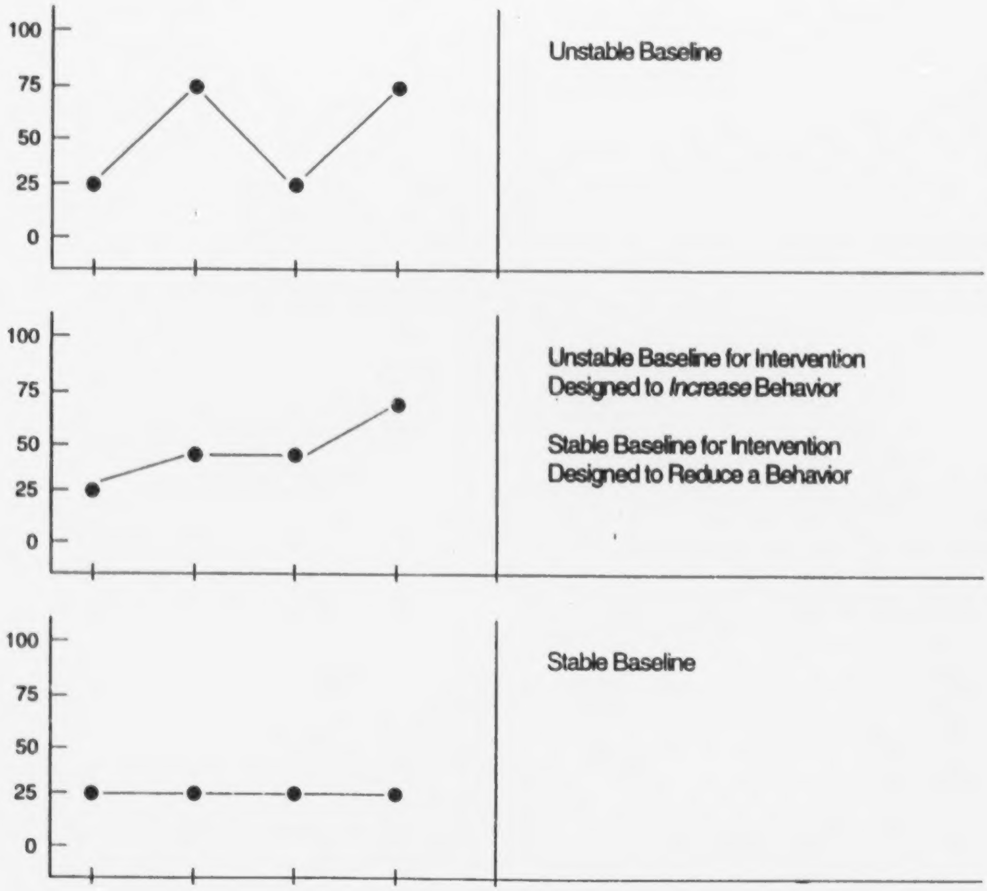
Figure 3 illustrates stable and unstable baseline. Generally, a baseline is considered to reflect a stable trend in behavior when the rate of behavior is steady or if it continues in a direction that is the opposite of the expected intervention outcome (e.g., a decreasing trend in rate of adaptive behavior when the intervention is designed to increase adaptive functioning). A minimum of three data points that indicate a definitive trend in responding is recommended. Baseline rates can at times be quite variable. In these cases it is important to continue collecting baseline data until either a definitive trend occurs or until a pattern of variability is established. There are ethical and practical limitations to extended baselines. For example, withholding an intervention designed to address severe aberrant behaviors until a stable baseline occurs may be problematic. The school psychologist needs to collect at least enough baseline data to demonstrate preintervention levels of responding.

The requirement for stability in the student's performance applies to all phases of an intervention. Thus the length of each phase and the changes from one phase to another are governed by the behavior measured. If changes in behavior occur and rival hypotheses are controlled, the influences that bear on a student's learning can be identified systematically.

Single-case experimental designs control for rival hypotheses in the following ways: (a) by introducing or withdrawing variables, (b) by immediately responding to and recording effects, and (c) by independently replicating effects (Rush et al., 1988). These factors control for rival hypotheses because the introduction of an intervention following baseline results in an immediate change in the level of student responding. Behavioral trends can also be influenced by withdrawing the intervention. Because both the introduction and the withdrawal of intervention result in behavior change, we can infer a cause–effect relationship between the intervention and the student's behavior change. Moreover, the introduction and/or withdrawal of the intervention must result in a relatively immediate impact on trends in the student's behavior. If behavior change only occurs after several intervention trials, then it is possible that extraneous variables have influenced the observed behavior changes. Finally, when the student's behavior change is replicated, one can be more certain that the intervention resulted in behavior change. With single-case designs, replication is demonstrated with the individual student across time, settings, behaviors, or personnel. In addition, the intervention may be replicated across students or classes of behaviors.

In the following sections we will review one case study method and three types of single-case experimental designs. The case study method, while lacking the experimental control found in single-case designs, is a useful method of documenting behavior change in students and is often the basis for a more formal and empirical evaluation of interventions. Single-case experimental designs can be classified into three major categories: (a) reversal; (b) alternating treatments; and (c) multiple baseline, multiple probe.

FIGURE 3. Stable and unstable trends during baseline.



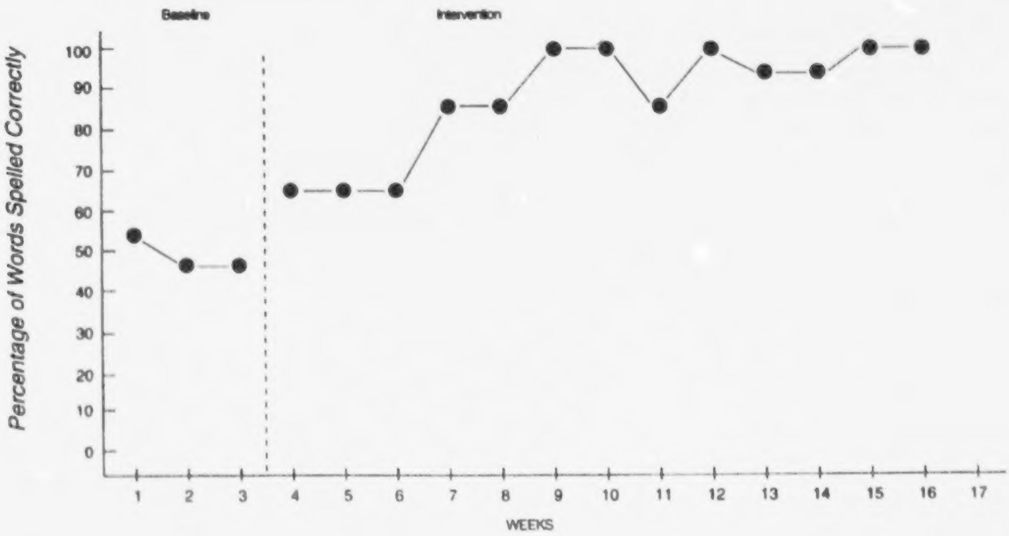
Case Study Method

The case study method involves a baseline (A) phase and an intervention (B) phase. With this method, baseline measures are repeatedly taken until stability is achieved. The intervention is then introduced and an appropriate number of measurements are made during this second phase. If behavior improves during the intervention phase, the effectiveness of the intervention is presumed to be demonstrated. Figure 4 illustrates an example of the case study (AB) method. The results of this intervention suggest that the improvement in spelling scores is directly related to the token economy intervention that was implemented beginning with session four. However, we don't know if the behavior change resulted from the treatment or from extraneous variables, or whether spelling skills would have increased naturally without the intervention. Thus, while the AB method may be useful for documenting a student's progress, it does not allow us to evaluate the efficacy of the intervention. To control for rival hypotheses, to demonstrate intervention effectiveness, and to demonstrate accountability, the school psychologist needs to use single-case experimental designs to evaluate interventions.

Reversal Design

This design is identical to the case study method except that following the intervention phase a return to baseline phase is introduced (i.e., ABA). If the student's behavior is improved during the intervention phase and then deteriorates when the intervention is withdrawn, the effectiveness of the intervention has been demonstrated. In short, with a reversal design, positive intervention outcomes occur *only* when the intervention is being implemented. A major concern with this design is an ethical one, since the intervention is terminated with the student *not* receiving an

FIGURE 4. Case study method for documenting behavior change.



intervention that has been demonstrated to be effective. To address this issue, a return to the intervention phase is recommended (i.e., ABAB). In short, the ABAB design is identical to the ABA design with the addition of a replication of the intervention strategy. In addition to addressing ethical objections to an ABA design, the ABAB strengthens the conclusion about the effectiveness of the intervention by demonstrating positive treatment effects twice. Figure 5 illustrates the use of an ABAB design to evaluate the effectiveness of a picture prompt training procedure to teach two students with mild disabilities to operate a microcomputer.

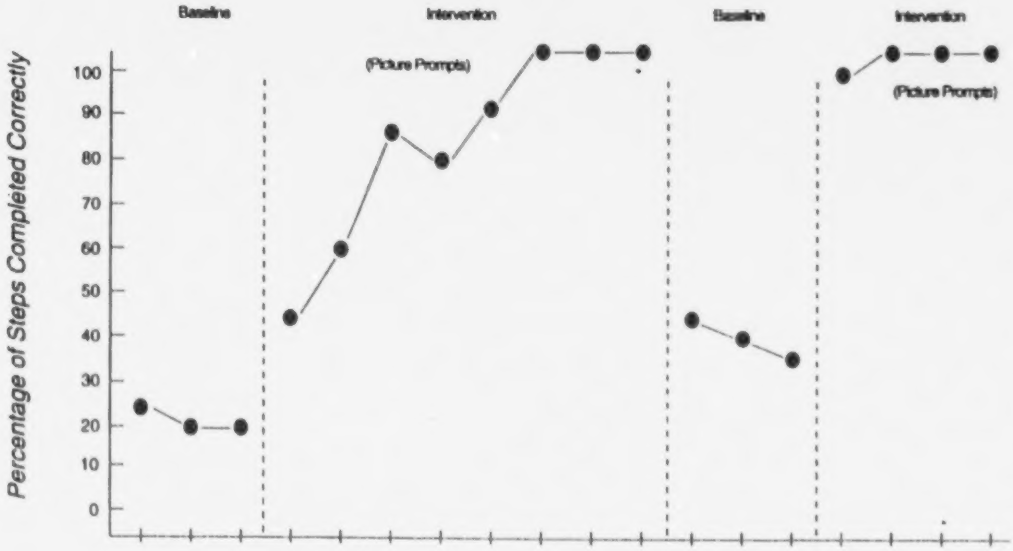
In this example, through consultation with the classroom teacher and observation of the student, the school psychologist hypothesized that a picture prompt training procedure would increase the student's microcomputer skills. The school psychologist developed an intervention that taught the student how to perform a series of steps in operating a microcomputer (e.g., turn on computer, select appropriate software, etc.). The psychologist hypothesized that picture prompts would guide the student's performance and that without the picture prompts the student would need frequent instructional prompting from the teacher. To confirm these hypotheses, the school psychologist identified a series of steps and photographed each step of the task analysis.

During the 3 days of baseline, the student performed less than 20% of the steps of the task analysis independently. During the fourth session, the picture prompt training was initiated with the student, and by the tenth session the student was consistently using the picture prompt procedures to operate the microcomputer. To determine if the intervention procedures were resulting in the gains in performance, *and* to determine if the intervention was continuing to maintain task independence, the school psychologist prompted the student to operate the microcomputer *without* the picture prompt strategy. When the picture prompts were removed (second A phase), the student's performance immediately decreased to baseline levels, suggesting that the increased performance during intervention was a result of the picture prompt strategy. Because it would be unfair to the student to discontinue the intervention, the school psychologist replicated the training phase of the intervention by reintroducing the picture prompt strategy (second B phase). This resulted in an immediate increase in microcomputer operation. The effect of the removal of the picture prompts on the student's behavior and the subsequent improvement in behavior following reinstatement of picture prompts demonstrated experimental control over the behavior, and thereby demonstrated empirically the effectiveness of the intervention.

Alternating Treatments Design

Alternating treatments designs are used to assess the relative effectiveness of two or more treatments (i.e., interventions) for a single subject. The basic strategy used in this design is the *rapid alternation* of two or more treatments, interventions, or conditions with a single subject (Barlow & Hersen, 1984). The alternating treatments design has been referred to by a variety of different terms: multiple schedule design, multielement baseline design, multielement manipulation design, and simultaneous treatment

FIGURE 5. Reversal design evaluating the effectiveness of picture prompt procedures.

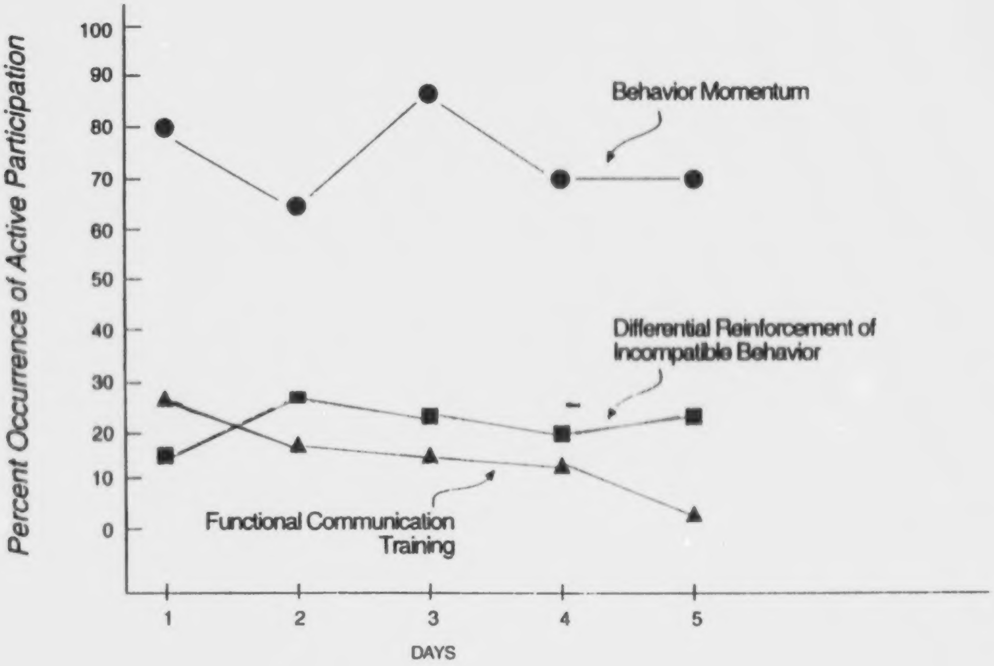


design. With an alternating treatments design, two or more treatments are presented to the student in a random or counterbalanced order. Because conditions are presented alternately, there should be no carryover effects with respect to behavior from one treatment trial to the next. In the procedure illustrated in Figure 6, the school psychologist used an alternating treatments design to evaluate the relative effectiveness of three intervention strategies that were designed to increase a student's active participation in educational tasks. The student, Darrell, had previously been evaluated by the school psychologist and it was determined through a descriptive analysis that Darrell exhibited high rates of oppositional behavior (i.e., verbally refused to participate in activities, failed to attend to tasks, etc.) and low rates of active participation (e.g., as indicated by visual engagement in tasks, verbal contribution to class discussion, etc.) in assigned cooperative learning activities. The results of a functional analysis of oppositional behavior suggested that these behaviors were motivated by negative reinforcement (i.e., escape from academic demands). The school psychologist consulted with the classroom teacher and support personnel, and the team developed three treatments based on assessment results, that they hypothesized would increase Darrell's active participation in assigned cooperative learning activities. These three treatments were: (a) behavioral momentum, a strategy involving the presentation of a sequence of demands or requests with which Darrell is likely to comply, at brief intervals immediately preceding the situations in which oppositional behavior typically occurs (e.g., Mace & Belifore, 1990); (b) differential reinforcement of incompatible (DRI) behavior, which consists of reinforcing the student for active participation in assigned task (e.g., Steege, Wacker, Berg, Cigrand, & Cooper, 1989); and (c) functional communication training (FCT), a procedure that teaches students, with subsequent reinforcement, to communicate a need for assistance from the classroom teacher (e.g., Carr & Durand, 1985).

The school psychologist began the intervention by determining a random assignment in the order of presentation of the three treatments. Next, the intervention team identified a specific context (e.g., classroom activity) that would be held constant across the presentation of the treatments. A 6-second whole-interval recording procedure was used to measure occurrences of active participation. The intervention team next implemented the three treatments in the following order: (a) behavioral momentum, (b) DRI, and (c) FCT. Following implementation of the three treatments, the team graphed the percentage occurrence of active participation relative to each of the treatments. The intervention team continued to implement the interventions across 5 days of evaluation as follows:

The results of the intervention clearly demonstrated that, relative to the other two treatments, the behavioral momentum strategy consistently resulted in higher rates of active participation. Thus, for this student, the intervention team could prescribe with confidence the use of behavioral momentum strategies as a method of increasing active participation.

FIGURE 6. Alternating treatments design to evaluate the relative effectiveness of interventions.



Multiple Baseline Designs

Multiple baseline designs are frequently used to evaluate the effectiveness of interventions, particularly for those interventions in which it is not practical to utilize a reversal, those in which the target behavior is not expected to reverse if the intervention is taken away, or those for which maintenance effects are anticipated.

Multiple baseline designs are an extension of the case study methodology. With multiple baseline designs, causal relationships between the intervention and its outcomes are inferred according to the following criteria: (a) continuous measurement of a behavior across a minimum of two baselines, (b) lagged introduction of treatment across baselines, (c) immediately measured effects of intervention, and (d) no observable effects in conditions in which the intervention has not been implemented (Rush et al., 1988).

There are three basic types of multiple baseline designs: across behaviors, across subjects, and across settings. Multiple baseline designs can also be used with groups of students. With multiple baseline designs, baseline data are collected on several behaviors for one student, one behavior for several students, or one student in several settings (Gay, 1992).

Multiple baseline designs can be used to evaluate the effectiveness of a variety of interventions across behaviors, students, or settings. For example, the school psychologist may use a multiple baseline design across behaviors to evaluate the effectiveness of an intervention to sequentially teach a student with developmental disabilities three different community living skills (e.g., laundry skills, public transportation skills, personal grocery shopping skills). Utilizing a multiple baseline design across students, the school psychologist could evaluate the effectiveness of a social skills training intervention to increase prosocial behavior of five students in the context of a mainstream class. Similarly, the school psychologist could use a multiple baseline design across settings to evaluate the effectiveness of a social skills training intervention to increase prosocial behavior of one student in five educational settings.

A variation of the multiple baseline design is the multiple probe design. The multiple probe design involves the same components as the multiple baseline design except that fewer measures of the dependent variable are required. The multiple probe design is used as an alternative to extended baseline phases when repeated measurements would lead to possible changes in behavior, thereby resulting in an unstable baseline, or when repeated measures during extended baseline are potentially harmful to the student. Any combination of these designs is possible. For example, Steege, Wacker, and McMahon (1987) used a multiple baseline and multiple probe design across behaviors to evaluate the effectiveness of stimulus

TABLE 2
Order of Implementation

Day 1	Behavioral momentum	DRI	FCT
Day 2	DRI	FCT	Behavioral momentum
Day 3	FCT	DRI	Behavioral momentum
Day 4	DRI	Behavioral momentum	FCT
Day 5	Behavioral momentum	FCT	DRI

prompt strategies in teaching complex community living skills.

To illustrate the multiple baseline design, a case example is presented in which a school psychologist and a classroom teacher collaborated in the design of a self-monitoring intervention to increase on-task behavior during independent seatwork sessions for three students who displayed low rates of sustained attention.

The classroom teacher and the school psychologist piloted the intervention with three students (Lisa, Matt, and Daniel) to evaluate the efficacy of self-monitoring. They used a multiple baseline across students design because they hypothesized that since the students were expected to acquire self-monitoring skills, a reversal design was not applicable. Moreover, they reasoned that by sequentially replicating intervention effects across students following stable baselines, experimental control would be demonstrated. Figure 7 illustrates the components of the multiple baseline design across three students.

Using a 10-second whole-interval recording procedure, the school psychologist observed each of the students for 10 minutes during an assigned independent seatwork activity for three consecutive days. Beginning on the fourth day, the classroom teacher provided in vivo coaching with Lisa in the use of a self-monitoring procedure. Baseline measures of on-task behavior continued with Matt and Daniel. On the fifth day of the project, the classroom teacher again implemented the in vivo coaching of self-monitoring, and Lisa exhibited increased gains in on-task behavior. In contrast, and as a control, Matt and Daniel continued to maintain steady rates of on-task behavior. On the sixth day, the classroom teacher provided the third session of coaching in self-monitoring with Lisa and the first session of coaching in self-monitoring with Matt. This resulted in an increase in on-task behavior for both students. Daniel, who had not been exposed to the intervention, continued to display steady rates of on-task behavior. The seventh day of the project was identical to the previous day. Beginning with the eighth day, all three of the students were coached in the use of the self-control procedures. As for Lisa and Matt, the intervention resulted in an immediate increase in on-task behavior for Daniel. In vivo coaching by the classroom teacher continued through the 13th session, each of the students maintaining high rates of on-task behavior. Beginning with the 14th session, the classroom teacher discontinued the intervention with each of the students. The school psychologist continued to measure rates of on-task behavior, during the 5-day maintenance and the 4-week follow-up phases. The students maintained high rates of on-task behavior throughout these phases. This intervention demonstrated that in vivo coaching in self-monitoring techniques resulted in increases in on-task behavior for Lisa, Matt, and Daniel.

DISCUSSION

This chapter introduced some of the underlying assumptions and strategies for reliably measuring change in students' behavior and for systematically evaluating the effectiveness of interventions. Systematic evaluations of interventions result in improved programming for students and increase the quality of school psychology services. School psychologists become accountable for their services by collecting data about student behavior and by establishing a causal relationship between an intervention and its outcome. This is becoming increasingly important, since consumers of school psychology services are no longer content to accept intervention services solely because the practitioner has been trained in their application, or because practitioners have had previous "success" using the intervention with other students, or because others provide testimonials about the skills of the practitioner. Consumers of psychological services are increasingly interested in objective measures of treatment efficacy (Sulzer-Azaroff & Mayer, 1991). Students, their families, and the professionals serving them deserve objective analyses that demonstrate that interventions are responsible for improvements in the students' behavior. The best practices method of documenting and confirming the effectiveness of interventions is through the use of direct measures of behavior and single case experimental designs.

ANNOTATED BIBLIOGRAPHY

Barlow, D., & Hersen, M. (1984). *Single case experimental designs: Strategies for studying behavior change*. Elmsford, NY: Pergamon.

This volume offers a thorough review of the issues and procedures involved in the use of single-case experimental designs to evaluate clinical interventions that include an in-depth discussion of methodology and provides multiple examples of a wide variety of designs.

Kazdin, A. (1982). *Single-case research designs: methods for clinical and applied settings*. New York: Oxford.

This volume focuses on the application of single-case experimental designs in the evaluation of the effectiveness of clinical and educational interventions. Kazdin offers a variety of examples of single-case experimental designs that clearly demonstrate the use of these designs in applied settings.

Rush, F., Rose, T., & Greenwood, C. (1988). ***Introduction to behavior analysis in special education.*** Englewood Cliffs, NJ: Prentice-Hall.

This volume discusses the use of applied behavior analysis procedures in addressing the acquisition of adaptive behaviors and the decrease of maladaptive behaviors with students who evidence behavioral, developmental, and learning disabilities. Rush, Rose, and Greenwood devote two chapters to the measurement of student behavior and one chapter to strategies for evaluating student progress. They give particular attention to the application of reversal, multiple-baseline, alternating treatments, and changing-criterion single-case experimental designs in the evaluation of educational interventions.

Sulzer-Azaroff, B., & Mayer, G. (1991). ***Behavior analysis for lasting change.*** New York: Holt, Rinehart, and Winston.

Sulzer-Azaroff and Mayer offer a text in which they describe the scientific technological, and professional practice of applied behavior analysis in educational settings. They offer chapters that focus on issues related to the selection of intervention strategies, identification of goals and objectives, measurement, and analysis of student behavior, and methods of evaluating the effectiveness of interventions. Several chapters are devoted to methods of teaching skills to students and in reducing aberrant behavior.

Best Practices in Interviewing

Francis E. Lentz, Jr.
University of Cincinnati

Barbara A. Wehmann
Hamilton County (OH) Office of Education

OVERVIEW

> "Interview ... a meeting face to face; usually a formal consultation." (Webster's Collegiate Dictionary)

Interviewing is one of the (if not the) most widespread and important procedures in the delivery of school-based psychological services. It plays a critical role in consultation, counseling, group problem solving, systems change efforts, and program evaluation. It is also the process through which the psychologist interfaces with consumers of services and must ultimately effect changes to solve problems. Traditionally psychologists have used interviews in both structured and unstructured ways, in diagnosis and classification, and as part of direct (counseling) and indirect (consultation) intervention processes.

All interviews have some common structure: verbal and nonverbal exchanges of information between an interviewer(s) and interviewee(s), content related to some purpose, and decisions resulting from the interview. These characteristics are clearly related to the basic characteristics of psychological assessment: the collection and analysis of information in order to make various decisions related to resolving problems.

Interviews are part of assessment and evaluation at the most basic level. However, for psychological services such as counseling or consultation, the goals of an interview may go beyond assessment processes and involve verbal attempts to change the behavior of the interviewee. For example, interviews within consultation may have objectives of changing interviewee behavior towards a referred child and counseling interviews usually include efforts at therapeutic changes in the client. These additional characteristics of interviews make writing a brief chapter on best practices in interviewing difficult.

This chapter will primarily examine interviews as methods of *assessment* within the problem-solving process: individual or group consultation, group problem-solving processes, and counseling. Even so, in a brief chapter it is impossible to discuss all aspects of interviews for every type of problem examined by school psychologists. The similarities among interviews used in different types of problem solving will be viewed within an ecological and behavioral framework.

It is important for school psychologists to consider the reliability and validity of interview information just as carefully as they consider how qualities of standardized tests (AERA, APA, & NCME, 1985) relate to meeting educational needs of students. Interviewing is sometimes treated too casually by practitioners, and this casual approach makes solving school problems even more difficult. This chapter's authors believe one of the best ways to avoid this casualness is by increasing knowledge about the important characteristics of a most basic tool, interviewing. Perhaps most importantly, interviews should be treated as carefully as any standardized assessment method.

COMPONENTS OF AN EFFECTIVE INTERVIEW

Effective interviewing, like all assessment procedures, is a multifaceted process. First, there must be some clear need for information during problem solving that the psychologist decides to partially meet by using an interview. (For the remainder of this chapter the terms psychologist and interviewer will be used interchangeably.) Secondly, groundwork must be laid within the school (system) so that other professionals understand the reasons for structured interviews and what information to expect from them. Understanding the reasons for structured interviews is seldom a naturally occurring event within a school building. Third, there must be an effective communication process so that interviewees and interviewers develop mutual trust, understanding, and the ability to collaborate (especially during consultative interviews). Without this type of relationship, interview data are likely to be inaccurate and probably not very useful.

607

Fourth, the content of an interview, especially questions and responses on the part of the interviewer, must be purposefully structured and made specific to both the interview purpose and type of presenting problem. Fifth, the psychologist must make explicit decisions on how to use the data from any interview, especially in regards to subsequent efforts with a case. Finally, the psychologist must understand the threats to inferences about necessary treatment that are influenced by interview information. These components will be explored in detail in the subsequent sections.

Principles for Effective Interviewing

Typically, the school psychologist is presented with some problem by teachers, parents, or students. It is difficult to imagine any school-based referral being satisfactorily processed without the use of one or more interviews. As part of the most traditional psychological service, namely classification for special education, the purpose of interviews has been to aid the classification decision. Interviews of adults and children, structured and unstructured, have been developed and studied in terms of reliability and validity specifically for this and related *diagnostic classification* (e.g., Hodges, Cools, & McKnew, 1989; Landau, Milich, & Widiger, 1991) with mixed results, especially in terms of often poor agreement across interviewers. Placing children in diagnostic categories has a long history in both clinical and school psychology. However, formal classification of problems has yet to demonstrate clear benefits to those who are classified. Discussion of interviews specifically related to this purpose will not be included in this chapter.

In terms of assessment for problem solving, however, there are several critical principles for conducting any type of interview that should be used as guidelines for best professional practice.

1. Interviews should always be ecological in nature (Barnett & Zucker, 1990) and directed toward the examination of variables in natural problem situations, the observable behaviors that resulted in a referral to a psychologist, and the beliefs and perceptions of the interviewee.

2. Before beginning the interview, the interviewer should set explicit desired outcomes, and these outcomes should be clearly related to making subsequent practice decisions.

3. Interviews must be focused and economical. This requires that the interviewer use questions and statements to control or direct the course of the interview. Control in this case does not mean telling the interviewee what to do and is not antithetical to collaboration. However, because school time for interviews is always limited, the maximum amount of information must be gleaned from an interview, and rambling, disjointed interviews are unlikely to be productive.

4. When the objectives of any interview have been clearly established, best practice dictates the use of structured questions and responses clearly related to achieving those objectives. Interviewer questions or responses are similar for any interview with the same general purpose (e.g., problem identification, problem analysis, or evaluation of treatment integrity). The *specific content* of verbal behavior during interviews will vary widely depending on the nature of the presenting school problem that resulted in a referral. For example, the content of questions during problem identification interviews (during counseling, consultation, etc.) will be quite different for academic versus behavioral concerns or for other presenting problems (e.g., possible depression vs. suspected sexual abuse vs. poor social skills [e.g., Mash & Terdal, 1988]). The interviewer will have to select questions most relevant to making good decisions about the presenting problem.

5. The interviewer must be aware of being an active listener and practice the verbal and nonverbal aspects of this important communication skill.

6. There should be an explicit plan to connect interview information to decisions about what the next professional actions should be. These decisions can include selecting additional assessment activities to extend or confirm interview information, integrating different sorts of available information, or altering intervention plans.

7. The interviewer should clearly understand how interview data can threaten the validity of any problem-solving process. Validity should always ultimately relate to positive outcomes for clients of services.

Clarifying Purposes for Interviews During Problem Solving

Within problem-solving assessment, interviews as assessment procedures may be classified along two broad dimensions. The first has the interview viewed strictly as an assessment method, whose purpose is to measure relevant variables and provide information for problem identification, analysis, and resolution. In this category, interviews are employed just like any other assessment method, like interviewing a child to collect information related to analyzing a reading problem so that an intervention may be planned.

The second category involves interviews used as the procedure during which two individuals collaborate. They exchange information that will be *immediately* used to plan or analyze a problem and evaluate some intervention. The interviewer collects information (often soliciting interviewee opinions about data already collected), elicits interviewee input on prioritizing multiple problem behaviors, and guides planning for the type of intervention that may be appropriate.

A single interview may serve both of these functions. An example is a problem identification interview between a consultant and a classroom teacher who has referred a student. In this case, the interviewer is collecting assessment information that will subsequently be used to guide practice, to help analyze the problem, to plan an intervention, and/or to set treatment responsibilities. In short, the information from the interview is to be used like any other assessment data. At the same time, the interviewer is soliciting interviewee perceptions about the relative seriousness of various problems, ensuring that they both understand the nature of the referral, and soliciting interviewee acceptance of problem definitions. This information is immediately employed within problem solving.

Effective interviews are driven by clear assessment goals. It is useful to consider the sequential purposes of interviews as part of school-based problem solving. An interview used at any point within the problem-solving process would have specific objectives that are seen as common across both a variety of theoretical approaches to solving problems and types of service delivery (e.g., counseling or consultation).

Bergan and Kratochwill (1990) present a model for behavioral consultation, and Cormier and Cormier (1991) for counseling, that provide clear examples of objectives of sequential interviews during problem solving: problem identification; problem analysis; intervention planning; evaluation of treatment progress and treatment integrity; and treatment evaluation. To these is added an initial purpose, which is screening for disposition of a referral (Hawkins, 1979). An effective interview should be conducted with one or more of these objectives.

Table 1 provides a list of core (not all) objectives (and related decisions) for the most common types of interviews related to problem solving within school psychology (for a more complete list of objectives see Bergan & Kratochwill, 1990, and Gutkin and Curtis, 1990). For each type of interview, the focus is on the types of objectives that need to be met, and examples of interview purposes beyond information collection are included. These objectives are common for interviews of various people (teachers, students, etc.) and service delivery methods (e.g., counseling or consultation).

More specifically, each interview in the problem-solving process will provide information that will guide the psychologist/interviewer in making decisions about future actions. For example, when the school psychologist is conducting the initial interview of a referring teacher or student, the most immediate decision is whether the psychologist should continue to be a prime change agent or whether the problem should be immediately referred to another source (as in the case of suspected child abuse). If the decision is for the interviewer to continue to have immediate responsibility for the referral, then a problem identification interview is begun immediately during the same meeting (or as soon as possible). Of course, even a decision about making a referral to another helping agent may require an interview of someone else to confirm critical information, and information could be received at any point in processing a referral that may require the psychologist to refer to another change agent.

In addition to the purpose of identifying the variables observed by the teacher that resulted in referral, information from the initial interview will be used by the psychologist to decide on which additional assessment procedures (including other interviews) may be needed (e.g., observations, child interviews, tests). The order for conducting more specific assessment (e.g., to observe in the class before interviewing the referred child) that will be needed to solve the referred problem must also be decided. These are critical decisions and may spell the difference between ineffective and inefficient psychological services and effective problem solution. Every interview will result in information being collected that will affect subsequent practice decisions. In this regard, psychologists need to limit the scope of questions during interviews to those relevant to helping the child, and not those about some issue in which the psychologist may have curiosity!

Failure to remain focused on objectives during the interview can have detrimental effects on the process of problem solving. This chapter's authors have been involved in training school psychologists and intervention assistance teams for a number of years, and it is their personal experience that one of the biggest barriers to effectiveness is for interviewers to lose sight of the purpose of an interview and "drift" aimlessly. This usually occurs during problem identification with the team, interviewer, and/or interviewee spending much valuable time "admiring" how "bad" a referred student is, even before defining the problem(s)! Everything is discussed endlessly, such as past transgressions, intransigence of parents, problems with previous siblings, and the like. However, no referring problems are clearly and specifically defined. The meeting ends with no objectives being met beyond agreeing that the referred child is the Mona Lisa of referrals.

In summary, the first step in using interviews effectively is for the psychologist to clearly understand the specific objectives of the interview and the types of decisions that will be influenced by interview information. Once these objectives and decisions are clearly understood, then the particular informational content needed for any type of referral, and the ver-

TABLE 1
Examples of Objectives and Decisions Related to Typical Problem-Solving Interviews

Phase of Problem Solving	Type of Assessment[a]	Objectives/Decisions[b]
Screening	1	a. case disposal
Problem identification	2	a. define problem b. describe problem settings c. prioritize problems d. select baseline data/method e. initial quantification of defined problems f. establish baseline responsibilities g. set contact schedule h. establish relationship • *what additional assessment is needed?* • *schedule for assessment?*
Problem analysis 1. Data collection interviews (could be multiple, different sources — parent, child, teacher)	1	a. collect interview data to help analyze problems
2. Problem analysis interview (consultation or counseling)	3	a. examine and clarify assessment data b. examine baseline data c. verify problem; set treatment goals d. form hypothesis e. select/plan intervention and responsibilities f. verify data collection g. set schedule • *what are the reasons for the problem to exist?* • *what are the most critical target behaviors?* • *which acceptable treatment matches hypothesis?* • *what is the treatment goal?*
Progress monitoring (brief contacts to review data and decide about needed change)	3	a. compare progress data to goals b. verify treatment integrity c. recycle if necessary • *is intervention working?* • *how well has treatment been implemented?* • *If there were multiple objectives, do we start on next goal?* • *should we continue as is or recycle to earlier phase?*
Plan evaluation	3	a. evaluate goals/data b. discuss general implications c. plan the fading of treatment d. establish ongoing data collection or terminate interview • *should the intervention be stopped?* • *how should it be ended?*

Note. This Table is adopted from several sources, including Barnett & Carey, 1992; Bergan & Kratochwill, 1990; Gutkin & Curtis, 1992.

[a] 1 = prime assessment function, 2 = mixed function, 3 = interface for action.

[b] Decisions are in italics.

bal or nonverbal behavior that will be necessary to achieve goals, can be chosen.

Relationships and Interview Accuracy: Setting Expectancies, Effective Communication, and Active Listening

When interviews are considered as assessment procedures, it is important that interview data be accurate (related to actual events in problem environments or to real teacher/parent/student beliefs and attitudes) and that interference with accuracy be minimized. Practitioners need to understand the nature of forces that can prevent obtaining accurate or complete information. Likewise, they should both incorporate that understanding as they make decisions about interventions and take steps to minimize interference. Many variables can influence the accuracy of data from interviews: lack of trust, role conflicts, poor communication, and misunderstanding of reasons for a particular assessment technique. Perhaps the first step toward ensuring clear and accurate interview information is preparing interviewees for the interview.

Preparation and entry information. There is an increasingly strong Zeitgeist in school psychology toward practitioners becoming more heavily involved in practices directly benefiting school children (e.g., Graden, Zins, & Curtis, 1988); best practices in interviewing have clearly followed this path. To make interviewing the most effective force for such alternative services, practitioners should consider the preparations (interviewee, school, and district levels) necessary to effectively incorporate problem-solving interviewing into practice. This section will briefly describe preparing schools and individual interviewees so that interviewing is most effective.

First, it is important for practitioners to assist likely interviewees in understanding the purpose of typical interviews, the critical need for accurate timely interviews to solve school-based problems, and the likely interview structure. At the school level, this can at least partially be accomplished by teacher in-services designed to impart such knowledge. In-service workshops are particularly important when the nature of school psychological services changes or is in the process of changing, for example, from a refer-test-place practice to alternative problem-solving services. Failure to inform consumers of the nature of new methods, including the use of interviews that closely explore classroom environments, can result in teacher suspicions about psychologist motives and interfere with the accomplishment of interview objectives. If an interviewer is not careful, teachers may perceive the interviewer as critical of their teaching or even blaming them for the problem. Either of these will surely influence the interview outcomes!

Similarly, when interviewing someone (teacher, student, parent, administrator) it is critical to inform them of the goals and purposes of the interview, types of questions that will be asked, uses for interview information, and ways the interview may benefit the interviewee. Preparation for interviewing should be straightforward. See for example, suggestions for preparing consultees (Bergan & Kratochwill, 1990) or counseling clients (Cormier & Cormier, 1991). Not only is preparation important for producing good outcomes of interviewing, it is also the ethical thing for practitioners to do. This type of preparation is best done at the beginning of any interview and certainly can be modified for those who are interviewed repeatedly. Martens, Lewandowski, and Houk (1989a) demonstrated the positive effects of discussing the nature and purpose of problem identification prior to interviewing teachers to identify student problems.

Active listening and good communication. Interviewing is analogous to transmitting and receiving radio signals. There is some medium within which information is somehow encoded. In the interview, the "medium" includes all physical aspects of the interview situation, the problem situation, the characteristics of the interviewer and interviewee, and the communication process. Within this medium, specific types of information about a problem are sought, discussed, summarized, and eventually understood. This section will focus on the communication process and the variables that can distort information solicited during an interview. Unless the "medium" is ideal, a positive relationship between the interviewer and interviewee may never develop, and if not, then accurate information may never be transmitted.

A number of variables exist in a school setting prior to and during an interview that can have a negative impact on the usefulness of the interview. For example, a supervisor (principal) can direct a teacher to seek help from the psychologist about a child. Often this results in tension during the interview that prevents accurate information. Some problems are so disturbing to a teacher that perspective is lost, and again, information is distorted to the point of interfering with problem solving. Two general procedures can be used by a school psychologist to minimize these distortions. First, the psychologist needs to understand the culture of the school — and how it may have already "prejudiced" the information in the interview. Psychologists who actively seek to become part of the school community and who participate in school activities may already be trusted by staff and can, thus, circumvent this problem. Secondly, active listening and other effective communication processes should be part of interviews for any purpose.

Listening is a complex and surprisingly active process. The interviewer must not only be able to ask the correct questions to meet interview objectives but must discriminate and respond to interviewer feelings and emotions about the problem. Effective listening can create the warmth and genuineness that

TABLE 2
Brief Descriptions of Active Listening

1. *Decide* you are going to really listen prior to the interview.
2. Be alert, sit straight, lean forward slightly, maintain good eye contact, use appropriate facial expressions.
3. Make sure your goal is to clearly understand the message, not evaluate it immediately.
4. React with nods, comments, or questions when appropriate.
5. Let the interviewee finish before speaking.
6. Empathize with the interviewee both by actions/words and cognitively/affectively; try to put yourself in his/her shoes.
7. Ask questions when you do not understand or need clarification.
8. Concentrate on the person's nonverbal as well as verbal behavior (agitation, posture, facial expressions, etc.).
9. Do not start thinking about your personal reactions to the interviewee too soon.
10. Avoid hasty conclusions and *hypotheses* about the problem; you need all the information first.
11. Correct situational distractions (shut the door or window; request interviewee to talk louder if necessary).

most clinical theories agree are critical to helping relationships (but that almost no one is able to define clearly). Table 2 briefly summarizes the actions that an interviewer should take to appear more genuine and to solicit the most accurate information relative to the interview purposes (from Wehmann & Curtis, 1990; McKay, Davis, & Fanning, 1983).

Nonverbal behavior and detecting interviewee feelings. As Table 2 illustrates, it is important to detect the feelings of the interviewee concerning the presenting problem as well as to obtain more objective information. For example, if the purpose of the interview is to define the presenting problems, the interviewee could verbally agree to the interviewer's summarized definitions; however, voice tone and expression could indicate that the interviewee really did not agree. Additional questioning would clearly be in order. Also as will be discussed, generalizing conclusions across (and even within) cultures, different socioeconomic groups, gender, and combinations of these categories can be hazardous because the same nonverbal behavior may have drastically different meanings.

Other interview characteristics besides verbal content carry "messages" or affect the transmission and reception of assessment information. Nonverbal behavior, both on the part of the interviewer and the interviewee, will affect how well information is gleaned from the interview. Cormier and Cormier (1991) describe interviewer nonverbal behavior believed to be related both to interview success and to interviewees perceiving the interviewer as genuine. Despite the most carefully structured verbal behaviors, such variables as distance between people, interpersonal orientation, posture, eye contact, facial expressions, voice tone and level, rate of speech, and even arrangement of furniture can also affect how interviewees respond.

Meanings associated with these various nonverbal aspects of interviews can be culturally, ethnically, economically, and even gender specific, and different interpretations of meaning can seriously affect data collected within interviews. The idea of culturally specific nonverbal messages is one that practitioners must carefully consider as they plan and conduct interviews.

Given the large number of cultures within the United States it is literally impossible for every practitioner to become "fluent" with differences across and within cultures in terms of communication characteristics; however, being at least aware of which cultures one is likely to encounter is critical. Perhaps the best advice to practitioners is to not be afraid to seek help from others when confronted with different cultural or ethnic groups. Similarly, ethical practice demands that practitioners carefully examine their own biases and ways these biases may effect practice. The notion of the effects of bias on interview outcomes will be more completely discussed in a later section.

It is also true that both verbal and nonverbal content need to be modified when the interviewees are children. For example, Garbarino and Stott (1989) suggest that child interviewers use the appropriate level of language and terms, interview the child in familiar settings, and always keep in mind the subject of the interview and its meaning to the child. Best practices would indicate that self-awareness of interviewing style and nonverbal content, as well as practice in improving these, are also critical. These issues should not be taken for granted, and careful observation of self, of others, and of the practitioner by others can be helpful.

Unfortunately, most systems of intervention that include elaborate interview procedures do not combine clear guidelines about both verbal and nonverbal behaviors. For example, Bergan and Kratochwill (1990) include little content on the nonverbal aspects of interviews, while being perhaps the best guide on verbal structures of effective problem-solving interviewing.

Finally, nonverbal behavior on the part of the interviewer can affect how the interviewee responds to questions and attempts to seek information. If the interviewee does not trust the examiner or is less likely to discuss issues with a person who does not have certain of the interviewee's personal characteristics, then the validity of the interview is seriously affected. For example, more positive responses of testees to familiar examiners have been documented for performance on standardized tests (see Fuchs & Fuchs, 1989) and there is no reason to believe that interviews will be exempt from such differential effects of interviewer characteristics. The effects on child performance of familiarity of the examiner were far greater for low-income minority students than for Caucasian middle-class children

Verbal behavior required in all types of interviews. A number of interviewer verbalizations are used during almost any type of interview and to meet any type of interview objective: information-gathering questions, clarifying questions, paraphrasing statements, and summarizing statements. Clarifying (or verifying, Bergan & Kratochwill, 1990) requires the interviewer to state the information just received and verify that it is accurate ("So Ms. Smith, Betty turns in her homework about 40% of the time and is out of her seat about 5 times every 10 minutes?"), or to directly ask the interviewer to provide clarification ("Are you saying that John has no friends and that you have never seen another child invite him to play on the playground?").

Summarizing is one of the most important types of interviewer verbalizations; it allows both parties to be sure that they are on the same wavelength. For example, "Jody, this is what I hear you saying. You're frustrated because Tom has only completed 3 of his last 10 math assignments, and you're angry at Tom's parents because they ignore your phone calls. However, you're not sure what to do about it because they have even ignored your notes. Is that right?" Without periodic summarizations, the focus of interviews is often lost, which is one of the most common mistakes in school-based psychological interviews.

Because the focus of this chapter is on interviewing as assessment, information-gathering questions are of great importance. No matter what the interview's purpose is, the interviewer will be explicitly asking questions to get information related to the problem. For example, "John, what happens when you try to join a group in the cafeteria?" is an example of a likely question during problem identification. "Frank, after you finish your spelling homework, what happens next?" would provide information needed for problem analysis. Notice that both of these examples are *open-ended* questions; that is, they cannot be answered by a mere yes or no. This is always a best practice when seeking this type of information. Questions that can be answered yes or no could be appropriate, for example, when asking the interviewee to verify interviewer summarization of some issue.

Biases and Other Ecological Influences on Interview

Usefulness. Both interviewer and interviewee may possess biases or physical/cultural characteristics to which the other may respond in a biased manner. Race or ethnicity, gender, socioeconomic status, and even appearance of either party can influence the other. From the standpoint of desiring to collect accurate information from interviews, the issue of unwanted bias must be always considered. Some have suggested that behavioral interviewing, informing interviewees of the importance of accurate information, and clarifying the purpose of the interview may overcome any existing biases (Thomas, 1973). However, bias effects can even occur when interviewers or interviewees attempt to apply "knowledge" about general client characteristics (for example, from general research on African American culture) to a specific client to whom the characteristics do not in fact apply (Cormier & Cormier, 1991).

Other interview biases could manifest themselves during the course of an interview. For example, an interviewer with a negative bias toward homosexuals could be conducting a problem-identification interview with a student who has asked for help and realize that the interviewee may be experiencing a sexual-identity crisis. On the other hand, the interviewee could hold stereotypical beliefs about a group identity of the interviewer, and the interviewee bias could affect accuracy and completeness of information.

Perhaps the first issue for interviewers is to be aware of their own biases, make efforts to overcome them, be willing to seek assistance with a case where biases are likely to have an adverse effect, or even have someone else conduct the interview. The issue of bias in psychological services is an emotionally charged and important issue. Nevertheless, ethical practice requires service providers to be honest about the potential for bias and to be active in taking steps to ensure that bias does not adversely influence their professional practice which in this case involves conducting interviews. There are of course other aspects of service delivery beyond the scope of this chapter where cultural differences and/or biases can have serious negative impact on psychological service delivery. Any such problem would clearly impact the valid use of information data.

Negative interview situations. Finally, the ecology of the interview setting can seriously affect the ability to meet interview objectives. A good example of this may be seen in group interviewing of a referring teacher (usually within a building-level intervention assistance team or problem-solving team). If the team is not careful, teachers may become intimidated and feel like they are part of some inquisition as multiple teachers fire questions at them. Best practice may require teams to carefully orchestrate their questioning strategies, take special care to prepare referring teachers for the experience, or even have one team member conduct initial interviews. Subsequently, that member could act as the teacher's "advocate" during team meetings, assisting the teacher in clarifying problem issues to the team. One team known to the authors divides the types of questions to be asked among the team members (it is a small team); for example, one team member may summarize and another ask the information-gathering questions. (At a workshop in Louisiana, one team indicated that they even assigned a member the task of making empathetic statements to the interviewee to ensure that the interviewee felt validated for having asked for help.)

Matching Interview Content to Purpose

In any attempt to discuss best practices, the breadth of school psychological services unfortunately complicates things. School psychologists are expected to have an incredibly wide range of skills and knowledge related to the entire spectrum of school-based problems. They may encounter such different problems as reading or math difficulties, attention deficit disorder, childhood depression, school phobia, and sexual identity crisis. For each of these categories of difficulties, there are different aspects of the presenting problem and problem environments about which information is required. These special requirements require asking different questions during interviews.

As one example, consider the initial interview of a teacher who has concerns about a student's reading performance. Information allowing a clear definition and analysis of the conditions related to the reading problem is obtained through questions about issues typical to reading difficulties. In this case, information is needed about expected curriculum level, elements of the potent academic environment, student motivation, skill level, and various expected student academic behaviors (see Lentz & Shapiro, 1986). This content is at least partially different from the content necessary to analyze a student's refusal to go to school.

Another example of interview questions specific to a population and particular problem environment is found in the waking-day interview described by Barnett and Carey (1992). The general purposes of this interview are to define and prioritize problems of preschool children in both school and home. Additionally, the waking-day interview has the objective of identifying common family routines where problems are most prevalent and where natural intervention routines may be extended into an acceptable intervention. Table 3 summarizes the different content issues from these examples (no attempt is made to show every content issue, the table is illustrative only). It should be noted that within both of these examples, there are similar questions and other verbal behavior used by the interviewer — questions about immediate antecedents, frequency, and the like; summarization and feedback; and validation of concern.

Thus, best practices in interviewing require school psychologists to know and understand potentially important variables for an incredibly wide range of problems, even within their practice settings. Interviews related to different presenting problems are similar for the generic interview goals described in Table 1. For instance, questions about environmental variables surrounding a problem behavior or about attempted interventions are always asked by the interviewer. However, there will always be content questions specific only to particular types of presented problems.

Well-described systems for delivery of intervention-related services, such as the Bergan and Kratochwill (1990) model of behavioral consultation, describe interview objectives and consultant verbal behavior during interviews. However, mastering even the detailed process of behavioral consultation (including interviews) is insufficient without clear knowledge of potential types of interventions for particular problem situations. This knowledge is analogous to the necessity for knowledge about specific interventions for different types of school based problems.

Verbal behavior and interview purposes. Once objectives and needed information content are clarified, and the interviewer is prepared, best practices dictates that the interviewer use the means most likely to achieve the goals. The more general aspects of communication within an interview have already been discussed. Several additional characteristics define categories of interviewer verbal behaviors and their relationship to the purpose and effectiveness of interviews. Bergan and Kratochwill (1990) have one of the clearest conceptualization of interviewer verbalizations, and one for which some research data exist to help evaluate validity. Within this system, verbal "messages" are classified by source, content, process, and type of control.

For example, in one of the most extensive evaluations of interview-based behavioral consultation it

TABLE 3
Examples of Content Focus During Interviews
Related to Two Different Problems

Problem 1: Reading problem for elementary student; data needed for problem analysis collected in initial interview.

1. Expected curriculum placement
2. Appropriate curriculum level matching student skill
3. Current placement in curriculum
4. Type spent in direct instruction
5. Types of academic behaviors expected/required in curriculum
6. Specific behavior during group instruction (on task, oral answering of questions, reading rates, keeping place, etc.
7. Recent accuracy and completion of assignments
8. Typical feedback procedures
9. Typical contingencies for performance of curriculum tasks
10. Definition of competing/interfering behaviors
11. Available curriculum referenced assessment (chapter tests, etc.)

Problem 2: Behavioral referral of preschool student; data needed for problem analysis collected in initial interview.

1. If problems are identified sequentially by following the child through typical daily settings:
    a. waking up;
    b. getting dressed;
    c. eating breakfast;
    d. going to school/riding bus; entering building; independent activities; group activities; transitions; independent and group play; exiting school; riding home; entering home; chores; community settings; supper, with siblings or strangers; going to bed
2. Typical disciplinary style; specific for above problems
3. What change expected? How would it affect parent or teacher?

Note. examples are taken from Lentz and Shapiro, 1986; and Barnett and Carey, 1992.

was shown that meeting objectives of problem-identification interviews by specifically clarifying observable problem definitions (soliciting specific observable information, verifying understanding, etc.) had significant impact on the positive outcomes of interventions (Bergan & Tombari, 1976). Perhaps of greater relevance to practitioners, Miltenberger and Fuqua (1985) show that a carefully constructed self-help manual focusing on appropriate verbal behaviors can significantly improve interviewer skills in meeting objectives of behaviorally oriented assessment interviews. This source may be of interest to school psychologists who are interested in improving their interview skills related to problem solving.

While details are clearly beyond the scope of this chapter, practitioners should be aware that different types of questions, question content, summarization skills, and verbal feedback are associated with interview success. Success in solving problems results from structured, carefully controlled interviewer questions and statements. As stated early in this chapter, interviewing should not be informal and overcasual. Rather it should be goal driven and carefully structured.

Using Interview Data to Help Make Valid Decisions

Table 1 outlines the specific decisions abut psychological practice that are at least partially guided by interview information. Best practices in interviewing would have these decisions be made in a deliberate, explicit manner by psychologists and would require psychologists to clearly understand how interview data can affect the usefulness of treatment decisions. These decisions are always influenced by multiple sources of information and not just interview data. Part of best practices is to understand and to be able to clearly articulate how one has integrated information.

For example, if a decision is made to conduct classroom observations to verify teacher information given within a problem-identification interview, what will the psychologist do if information from the two sources is contradictory? An exact answer to this question would depend on the particular case. A decision would have to be made to actively collect more verification data (either interview or observation) or to go ahead and form an hypothesis about the reason for the problem, weighing one data source more heavily. However, the process of just collecting masses of data without a clear idea about how to integrate it is inefficient. It is perhaps analogous to the practice of giving five or six projective tests to "cover" all possible bases without any idea of what to do with the information or how to weigh the importance of the different tests.

Psychometric considerations of interview data. Psychologists are ethically bound to defend the selection and use of assessment procedures during practice (AERA et al., 1985). Thus, for any given purpose of conducting an assessment, the practitioner must clearly understand the reliability and validity of potential assessment methods prior to deciding which procedure is most appropriate. It is indeed unfortunate that the most widely used assessment practice, interviewing, is associated with a database quite sparse on the psychometric qualities of the information collected during interviews.

Arguably, one of the most important qualities of interview data is the degree of accuracy in relation to actual problem behaviors and ecological variables in problem situations. In terms of variables within environments, accuracy refers to the correspondence between collected data (in this case from interviews) and real-time events. Likewise, in terms of information concerning thoughts, beliefs, perception of interviewees, accuracy refers to the correspondence between interview data and the actual internal events (internal to the interviewee).

The behavioral assessment model seems the most appropriate for judging the qualities of interview data. For the problem-solving approach, this model is appropriate because the majority of interview data relates to behaviors and environmental variables within natural settings. Within this conceptual framework, interviews would usually be considered indirect because they almost always focus on retrospective measurement of events that have already occurred. The exception is when the focus is on the interviewee's current thoughts, perceptions, and the like.

In a behavioral assessment model, content validity is an issue (Linehan, 1980). Content validity for interviews relates to how well an interviewer samples the behaviors, settings, and ecological variables needed to resolve any particular problem. Lentz and Shapiro (1986) provide a description of the interview content related to academic problems.

Accuracy of interview information must be considered one of the most basic requirements, both technically and practically, in judging the adequacy of interviews. Treatment decisions cannot be made effectively in the absence of correct information or with distorted or inaccurate information. Data given by interviewees can be biased or not related to the actual events. However, if this is recognized, this knowledge becomes useful in understanding the dynamics of a referral. Note that to recognize such distortions assumes knowledge of what is actually true. Because data correctness is a prime issue for interviewing from a behavioral assessment model, the "truth" of data could be partially determined by examining the correspondence of data across interviewers and occasions and between interview information and other measures of the same behaviors. Of course, practitioners must make decisions about the reliability of interview data whenever they integrate information from different sources.

In a practical sense, integration of interview data can be conceived as a series of accuracy checks, although actual correctness of interview data is unlikely to be completely verified. At the end of any interview, a practitioner will make at least an implicit decision about whether to accept and act on the interview data or whether to employ other sources for extension or verification of information. This type of decision could be influenced by previous interactions with the interviewee and, unfortunately, by time constraints.

The final dimension of interview validity within the behavioral assessment model lies in the appropriateness of key treatment decisions: selection of treatment goals; formation of a hypothesis about why a presenting problem exists; correctly matching intervention characteristics to this hypothesis; making accurate decisions about whether treatment has been implemented with integrity; and correctly evaluating the significance of intervention results. Interview data will be involved to some extent in all of these decisions.

What is known about the validity of data collected from interviews used to make any of the decisions just listed? There are some data on appropriate content of interviews (actually on assessment packages) for a few types of problems (see Mash & Terdal, 1988, for examples). Some data exist on the relationships between specific interviewer verbal behavior within consultation and positive intervention results (Bergan & Tombari, 1976). For example, the clear definition of observable problems and verification of definitions by interviewees is related to success of problem-solving efforts. Amazingly, given the integral nature of interviews for any problem-solving approach, little other empirical guidance exists. The paucity of empirical knowledge was well described by Gresham (1984) and remains basically unchanged today.

In terms of social validity (for example, the acceptability of interview procedures, perceived significance of interventions developed through using interviews), a little more is known, primarily because existing research has focused on the process of interviewing rather than the outcomes. For example, Martens, Lewandowski, and Houk (1989b) identified several types of interviewer verbalizations significantly related to favorable ratings of interviews by interviewees. Generally, interviewer verbalizations primarily relating to being more directive in managing the course of the interview were viewed most favorably. While such social validity is important to understand, it does not necessarily clarify those types of interviewer behaviors most important in planning effective treatments.

Given the state of empirical information, how then may psychometric qualities of an assessment procedure (in this case interviewing) guide ethical school based practice? It seems reasonable to infer that structured interviews emphasizing well-defined goals and observable problem variables (even variables that may only be self-observed by the interviewee) rather than inferred constructs (psychological traits) are more likely to produce information that will assist in problem resolution. Content of interviews for specific problems has been published from successful treatment programs and may be used with more assurance of validity (see, for example, Barnett & Carey, 1992). Verbal and nonverbal behaviors that increase the acceptance of the change process (consultation for example) are partially identified, and guides such as Bergan and Kratochwill (1990) can be followed to increase the chances of success. Beyond this information, there are some other general guidelines that should increase the likelihood of both valid interview information and valid decisions made partially from interview data. These guidelines are summarized in the following sections.

Multiple sources and interview information. To ensure that information from interviews is accurate, practitioners need to carefully consider whether they need to actively verify interview information by examination and integration of data from other methods. An example is comparing information obtained from the teacher to information collected directly by observing in the classroom. Of course, interview data may be judged by the interviewer as accurate enough to be immediately used without such verification. It is likely that at times psychologist/teacher problem-solving teams may not even consider information other than that collected through interviews. This is not different from individual counseling where the psychologist/counselor relies on information from the therapeutic interviews to conduct ongoing therapy and does not collect independent verification.

The decision to use unverified interview information, or to employ multiple sources of information, is somewhat analogous to making a "leap of faith"; in fact psychological assessment must always involve such a leap. At some point, a psychologist must decide that sufficient information exists to make treatment decisions; it is in selecting this point that one must be careful. Some interview data are more easily checked than other types, for example, academic performance information (tests, homework completion, etc.) provided by teachers (i.e., Lentz, 1988). Other information may require more complicated efforts such as direct classroom observation (for example, information about the academic environment, regular classroom expectancies or contingencies).

Teachers may tend to report general rather than specific information about student classroom behavior and the referring problem. Part of the goal of a problem-identification interview is to clarify general descriptions into specific definitions. Likewise, teacher-reported information about student concern (or lack of) about the problems, or a child's willingness to change may be checked through student interviews.

In summary, best practice dictates that the psychologist make decisions about the necessity for multiple views of a problem in a conscious manner, idiosyncratically for the particular case at hand. Failure to make well-considered decisions about these issues likely will not enhance the success of problem solving.

Accuracy and inference. Of course, the fact that inaccurate information is collected during an interview may have its own significance in making treatment decisions. Teachers, parents, or other referring sources may well have a distorted view of actual behavior within real problem situations, and such a distorted view may have created the referral. However, unless the accuracy can be verified, the psychologist cannot make the inference that inaccurate perceptions are related to distorted views of a student by a referring source! Whether or not this type of distortion is suspected, the collecting of confirming information about the degree of reported behaviors may even assist the interviewer to change the perception of the referral source or to reframe expectancies about child behavior. Thus, to make valid inferences from interview data as to what actually occurs in problem settings, and to make valid use of interview data, accuracy must eventually be judged.

Treatment decision validity. Accuracy of any assessment data is necessary, but not sufficient, to make decisions about what actually needs changing, what level of change would satisfy the referring source and/or be developmentally appropriate, or which intervention may work the best. Examining the validity of these types of decisions has not received sufficient research. This is basically true from most types of assessment data, not just information from interviews. Within descriptions of such systematic procedures as behavioral consultation (Bergan & Kratochwill, 1990) or collaborative consultation (Gutkin & Curtis, 1990) are some suggested practices that will enhance the treatment validity of assessment practices including interviewing. For example, both of these approaches suggest that during interviews the consultant/interviewer solicits consultee understanding of information, validates target behavior selection by the consultee, and facilitates consultee willingness to make input into intervention design. These types of practical suggestions when incorporated into problem-solving processes are likely to produce more solved problems.

Finally, it should be clear that beyond assessing the accuracy of interview data, interviews are used as part of an assessment package and it is difficult to validate only a part of any package. The attempt to validate more traditional assessment procedures (for example, tests of cognitive ability) as stand-alone procedures seems also doomed to failure because such measures are almost never used alone in real practice.

Professional Development of Interviewing Skills

Use of effective interviewing procedures is neither natural nor simple. Unfortunately, it often seems that professionals who have not used structured interviews as part of the problem-solving process often assume that interviewing within this process will be easy and simple. Notwithstanding by using objective and behavioral procedures, psychologists can develop appropriate interview behaviors. Bergan and Kratochwill (1990) reviewed the research in training behavioral consultants, primarily in terms of interviewing skills, and concluded that structured and goal-directed training of interviewing skills was effective. Miltenberger and Fuqua (1985) demonstrated success with a majority of interview trainees by using clearly written instructions followed by practice; unsuccessful trainees with this method typically responded successfully to audio and/or written models. Both of these processes require practice and self-monitoring of clear observable behaviors as training goals. Mutual feedback between psychologists while practicing interviews can assist development of good skills, as can the use of videotapes. This chapter's authors have found both of these methods to be effective. In fact, without guided practice and feedback, *improvement* in interviewing procedures seems unlikely to occur.

Likewise, psychologists can develop skills necessary to integrate interviews into successful practice. As mentioned earlier, success in providing alternative intervention-oriented services requires development of many skills and a wide knowledge base: skills in integrating multiple data sources, skills in observation and alternative curriculum-reference assessment, skills in managing consultative problem-solving including interviews, and knowledge about a wide variety of often complex interventions for difficult problems. None of these skills by themselves will guarantee effective practice in the long run.

SUMMARY AND CONCLUSIONS

Interviewing has been presented as a major part of assessment and of intervention with school-based problems. Best practice with interviewing includes setting clear goals, structuring interviews to meet objectives, using appropriate verbal and nonverbal behavior to meet goals, and being aware of potentially biasing phenomena when interviewing. In spite of the importance of interviewing, it is a procedure without the support of an adequate research base. Because of the scanty database, empirical information that should normally guide ethical practice is lacking. However, there are procedures for psychologists to employ that will increase the chance of using interviews in a valid manner. Likewise, the means to acquire adequate interviewing skills are available if psychologists are willing to engage in structured professional development activities. Given the stakes involving misuse of such an important service component, developing and refining adequate interviewing skills and content knowledge related to typically encountered problems should be a priority.

ANNOTATED BIBLIOGRAPHY

Bergan, J., & Kratochwill, T. (1990). *Behavioral consultation and therapy*. New York: Plenum.
This is the most complete and comprehensive guide to behavioral consultation (and general problem-solving consultation) that currently exists. Clear discussion of well-defined verbal behaviors within interviewing, the purposes of interviews, research into consultation, and consultative interviewing are included. This should be in the library of all practitioners.

Cormier, W., & Cormier, L. (1991). ***Interviewing strategies for helpers: Fundamental skills and cognitive/behavioral interventions.*** Pacific Grove, CA: Brooks/Cole.
While going far beyond interviewing skills, this book has excellent sections on interviewer characteristics, nonverbal aspects of interviewing, active listening, and the role of interviewing within a general problem-solving process.

Garbarino, J., & Stott, F. (1989). ***What children can tell us: Eliciting, interpreting, and evaluating information from children.*** San Francisco, CA: Jossey-Bass.
This is an excellent volume with extensive guidance about conducting interviews of children around a wide range of problems (sexual abuse, divorce, etc.). Settings and issues are covered that extend far beyond schools, but the content would be of extreme importance to any school psychologist who interviews children as part of assessment or during counseling.

Hughes, J. (1990). *The clinical child interview*. New York: Guilford Press.
An excellent addition to the school practitioner series that covers all aspects of child interviewing for school practitioners, this book includes interviews to collect information on internal events, discusses issues in interviewing across different age levels, and provides guidance on good strategies in dealing with common problems in interviewing children.

Shapiro E., & Kratochwill, T. (Eds.). (1988). *Behavioral assessment in schools*. New York: Guilford Press.
While this is a more general book about behavioral assessment (and a good one), it does have several excellent chapters directly relevant to interviewing (see chapters by Alessi and Witt). In addition, parts of many other chapters are relevant to understanding the use of interviews for many different school-based problems.

Best Practices in the Systematic Observation of Classroom Behavior

John M. Hintze
University of Connecticut

Edward S. Shapiro
Lehigh University

Gary's teacher, Mrs. Yotter, reports that Gary has extreme difficulty remaining in his seat during instructional periods. In addition, Gary has problems maintaining his attention and frequently does not seem to listen. As a result, his classwork has suffered terribly. Recently he has become a behavior problem by interrupting and distracting other students. In an attempt to reduce these behaviors, Mrs. Yotter reports that she has tried moving Gary's desk to the front of the room next to her own, reprimanding him, and taking away privileges, all without success.

Danielle, a third-grader, is reported to be extremely shy and withdrawn. Her teacher indicates that she avoids her peers and other social interactions. During free time, Danielle prefers to be alone rather than with her classmates and rarely initiates interactions with others. Her teacher has attempted to increase Danielle's involvement by structuring play and activity situations that would encourage opportunities for social interaction. More recently, Danielle has been involved in social skills training with the school counselor. Although Danielle is improving in some of her social skills, evidence for change in her classroom has been difficult to document.

Finally, Mr. Kramer reports that a student in his class for children with multiple handicaps engages in self-injurious face slapping. Neither Mr. Kramer nor the classroom aides have been able to determine a pattern to these occurrences or the frequency with which they occur. Several interventions have been attempted, including verbal reprimands, physical blocking, and time-out, without substantial effect. As a result, mainstreaming opportunities have been decreased and there has been consideration of alternative placement in a more restrictive setting.

All of these are situations in which the practicing school psychologist may be called upon to consult at any given time. One means of evaluating these problems would involve the use of a variety of behavioral assessment strategies which could include administration of behavioral checklists, interviews, and anecdotal observations. While such methods are less time-consuming to administer, they may not result in data that directly reflect the frequency, duration, or intensity with which the problem behaviors are occurring. Additionally, although indirect methods of assessment such as interviews and informant reports offer important information about the perceptions of significant others concerning the problem behavior, the inherent limitations with each of these measures can leave both the referring teacher and school psychologist feeling less than satisfied with the information gathered and any interventions that may be implemented.

More than any other method of behavioral assessment, systematic direct observation represents the most direct and desired approach to data collection (Shapiro, 1987). The distinguishing characteristics of such procedures requires noting the occurrence of the behavior of interest in the settings where the problem actually has been happening. As such, the data are empirically verifiable and do not require inferences from observations to other behaviors. With direct and systematic measurement, an ongoing assessment of the individual's performance is obtained in the actual environment. In contrast, indirect measurement (e.g., the use of teacher or parent reports, interviews, or anecdotal observation) requires that inferences be made concerning what the informant reports and the student's actual performance in the setting of interest (Cooper, 1987).

Individuals using systematic direct observations will often develop their own code for performing observations. After the target behavior(s) is defined, the observer may conduct the observations using any of the techniques to be discussed. The assessment may include event recording; interval recording; and the noting of frequency, rate, or duration of behavior. It also may include the recording of antecedents, consequences, and setting variables that may be related to the target behavior. The versatility of deriving one's own system makes this technique quite desirable and relevant for all types of assessments, including those done in the school.

BASIC CONSIDERATIONS: RATIONALE FOR SYSTEMATIC DIRECT OBSERVATION

As the role of the school psychologist continues to move toward service delivery through consultation, methods of assessment that offer direct linkages to intervention development are critical. In all of the cases presented at the beginning of this chapter, the school psychologist was being called upon to help teachers solve problems. Clearly, the use of assessment strategies useful in making diagnostic classifications for placement in special education programs (i.e., published standardized, norm-referenced tests such as WISC-III, Woodcock-Johnson Psychoeducational Battery, etc.) will not provide the information needed to identify specific behaviors to target for intervention, potential treatment procedures, nor ways of monitoring whether implemented interventions are effective. Direct and systematic observational measures were specifically designed for these purposes.

A number of advantages to school psychologists in using systematic observation can be identified. First, systematic observation measures focus on the observable behavior of the student. As such, they provide a clear operationalization of the problem concerning the teacher. Through these methods, it becomes possible to target specific behavior for change. The impact of altering these behaviors can be discussed with the teacher so that meaningful behavior change can be accomplished. This emphasis on functional importance has consistently been emphasized as a key to effective service delivery (Gresham, 1985).

Second, systematic direct observation allows the school psychologist to function in a much broader role than does the traditional diagnostic model. Because assessment and intervention are closely linked, the school psychologist's assessment provides an opportunity for direct consultation to teachers. Instead of simply providing diagnostic data that teachers rarely have found useful, the psychologist may offer a set of intervention techniques and direction on the implementation of these strategies. This places school psychologists in a position to draw on many additional skills and provides them with the much preferred role of consultant.

Third, use of systematic direct observation provides opportunities for accountability. The findings of school psychologists are increasingly being challenged. Court cases such as *Larry P.* and *PASE v. Hannon* are strong evidence that school psychologists must assume responsibility for their actions. Because systematic direct observation offers individualized analysis of behavior change due to intervention efforts, their accountability can be objectively measured.

In short, when one examines the types of decisions to be made from assessment, clearly direct systematic observation is most closely linked to decisions about intervention planning and pupil progress. Referrals for evaluation can be conceptualized as a request for the development of intervention strategies that can help ameliorate the referral problem. In using a systematic direct observational methodology, the school psychologist can not only answer the question raised, but can also provide ongoing consultation and evaluation of the recommendations. In this way, the school psychologist remains accountable and operates in a role preferred by all.

BEST PRACTICES

Considerations in Selection of Target Behaviors

Determining social significance of behavior. More often than not, consultation with teachers and other school personnel will reveal a wide range of student behaviors that might be candidates for modification. Assessment information gathered during problem identification must be examined to determine which elements of a student's behavioral repertoire might yield socially significant and ecologically valid target behaviors.

Any procedure that affects behavior of one or more persons in ways that increase the probability or magnitude of benefits (reinforcers) for them or others are considered to be socially valid targets for behavior change (Hawkins, 1986). Thus, teaching children to read, pay attention, or make friends with peers is likely to be habilitative, because these efforts generally increase benefits and decrease costs for both the individual learner and the rest of society (Hawkins, 1991). A goal, outcome, or procedure is valid to the extent that choosing it actually improves the benefit-to-cost ratio for the individual, for others, or for both. A consumer's or professional's opinion about a goal, outcome, or procedure is only valid to the extent that it is consistent with such improved benefit-to-cost ratio (Hawkins, 1991).

Nevertheless, judgments about how much a particular behavior change will contribute to a student's overall habilitation (adjustment, competence) are difficult to make. The school psychologist, however, must place the highest importance upon the specification and definition of target behaviors that are truly useful (Kratochwill & Bergan, 1990). Reliance on subjective judgment as the first and only criterion ignores other objective possibilities.

One objective validation strategy is the use of normative data to estimate which behaviors are likely to be adaptive. For example, observing the rates of academic engaged time of "average" or even "ideal" students will aid the clinician in determining the extent to which the behavior of the target child is discrepant (Hawkins, 1991). In a similar fashion, systematically observing specific behaviors thought to correlate with objective outcomes of performance from that of a normative group may assist in determining which behavior(s) are of critical importance for success. Such a method will not prove that the measured behaviors are functional but will certainly suggest possibilities (Hawkins, 1991). Finally, the best validation of which behavior is most adaptive is to test experimentally the outcomes produced by different behaviors and different levels of their performance (Fuqua & Schwade, 1986). By definition, the performance yielding the greatest benefit at the least cost is the most adaptive (Hawkins, 1986). For example, Warren, Rogers-Warren, and Baer (1976) assessed the effect of different frequencies of children's offers to share materials. Measuring peer reactions of accepting the offer indicated that such acceptance was maximal when the target child made offers at middle frequency, neither very often nor very seldom. In this case, peer reaction was a critical measure of the target behavior's appropriateness because it is peer acceptance that should eventually maintain the behavior.

Antecedents and consequences of behavior. Direct systematic observation allows the school psychologist to focus on examining the interdependencies among functional antecedents, behaviors, and consequences (Alessi, 1988). In their most simplistic form, such procedures involve observing what occurs just before and just after the problem behavior. Careful examination of functional response chains may help answer very telling questions such as

- Are there avoidance, escape, or termination behaviors made by the student to requests or demands made by the teacher?
- Do these behaviors escalate with certain tasks versus others?
- Does the student demand behaviors from the teacher or peers?
- Is there an escalating pattern here, as the teacher or peer attempts to avoid these demands?
- What are the functional outcomes of these interpersonal sequences?
- Do such exchanges occur primarily in one setting over another or during specific times of the day?

According to Alessi (1988), finding differences is one thing; however, finding out whether these differences make a difference is yet another. Once hypotheses regarding behaviors are formed, school psychologists may test these postulates by asking the teacher to change just one variable, the one most likely to be related to the behavior discrepancy. If a reduction or increase in behavior follows, then this factor may be the only change the teacher need make. However, if the problem behavior is unaffected, another change is then substituted for the first. Such testing of hypotheses directly ties assessment to intervention and minimizes the teacher's burden by asking for only minimal changes in teacher behavior prior to the implementation of a formal intervention plan. Asking teachers to change the ecology of their classroom in a "least restrictive" fashion has been shown to increase the acceptability of proposed interventions (Witt, Martens, & Elliot, 1984) and to avoid the traditional comprehensive assessment process that usually consumes more staff resources and time merely to diagnose a problem than to resolve it using a strategic systematic assessment approach (Alessi, 1988).

Prioritizing possible target behaviors. In many intervention programs, decisions must be made about the relative priority of possible target behaviors. Sometimes the information produced by systematic observation methods points to one particular aspect of the student's behavioral repertoire in need of improvement. More often however, assessment reveals a constellation of related, and sometimes unrelated, behaviors in need of change. In most cases, all of these target behaviors cannot effectively be addressed at the same time. In other cases it is reasonable to expect that modifying one behavior will lead to multiple changes, both favorable and unfavorable. Thus, prioritizing is often appropriate. However, guidelines for prioritizing are not always clear.

Among the factors that might serve as guidelines, Nelson and Hayes (1979) have enumerated four: (a) alter the behavior that is most irritating to the mediator involved (Tharp & Wetzel, 1969); (b) alter a behavior that may be relatively easy to change (O'Leary, 1972); (c) alter behaviors that will produce beneficial response generalization; or (d) when responses exist as part of a longer chain, alter responses at the beginning of the chain (Angle, Hay, Hay, & Ellinwood, 1977). In addition, Hawkins (1986) has added a few others, some of which may overlap considerably with the four already listed. First, one should modify behaviors lower in skill hierarchy — the "keystone," "pivotal," or "foundation" skills — before modifying those higher in the skill hierarchy if there is, indeed, good evidence that one clearly depends upon the other. Second, one should give priority to behaviors that promise to have very general utility. For example, attention to task is useful in many aspects of a daily classroom functioning. A student who presents with difficulties in such areas should probably have that deficit remedied early in the intervention.

Third, the construction or acquisition of behavioral repertoires should take precedence over elimination of specific behaviors. In other words, it is important to focus on teaching new behavior rather than just eliminating unwanted behavior. Fourth, behaviors that gain the student access to natural environments where a variety of important behaviors will be taught or reinforcers made available should receive high priority. Such an approach maximizes the possibility that the behavior will be maintained over a long-term period after the specific intervention is completed. Fifth, behaviors given priority by the student should be preferred on the basis of the student's more extensive experience with the contingencies in his or her life. Clearly, the role of choice should play an important part in deciding which behaviors to target. Sixth, some behavior changes are urgent in the sense that the opportunity for a certain intervention may pass, the behavior may pose a serious risk to someone, or some temporally scheduled consequences of major importance (e.g., school suspension) may be imminent. Seventh, when a response chain is involved, one must sketch out alternative intervention plans and decide whether forward chaining or backward chaining appears more promising, and thus whether the first response or the last receives top priority.

Defining target behaviors and writing behavioral definitions. Before behavior can undergo systematic observation, it must be specifically defined. A good definition of a target behavior provides an accurate description of the behavior to be changed (and therefore measured), not an inference or an implication of behavior (Heward, 1987). Raising a hand to be called upon is an observable and measurable behavior. By comparison, being disorganized is not a description of any particular behavior; it merely implies a general class of responses. According to Hawkins and Dobes (1977), behavioral definitions must be explicit rather than implicit, and contain three essential characteristics:

> 1. The definition should be objective, referring only to observable characteristics of the behavior (and environment, if needed) or translating any inferential terms (such as "expressing hostile feelings," "intending to help," or "showing interest in") into more objective ones.
>
> 2. The definition would be clear in that it should be readable and unambiguous so that experienced observers could read it and readily paraphrase it accurately.
>
> 3. The definition should be complete, delineating the "boundaries" of what is to be included as an instance of the response and what is to be excluded, thereby directing the observers in all situations that are likely to occur and leaving little to their judgment. (p. 169)

Behavioral definitions must be objective, ensuring that specific instances of the defined target behavior can be reliably observed and recorded. Furthermore, a clear definition is a technological definition that enables others to use and replicate it (Baer, Wolf, & Risely, 1968). A complete definition identifies what is not the target behavior and aids observers in discriminating the target behavior from similar responses. It allows accurate recording of noninstances of the target behavior when of interest. Finally, behavioral definitions should be concise (Heward, 1987).

Measuring and Recording Behavior

There are various types of data that can be collected during direct systematic observation. The exact nature of the data is determined by the specific behavior observed, the frequency of its occurrence, or the particular interests of the observer (Shapiro, 1987). In addition, practical considerations such as the availability of observers, the amount of time the student is accessible, or any combination of these factors, all dictate the type of data collected. Because each of these data may yield different results, the method of data collection must be clearly understood.

Event recording. The type of data known as event recording involves counting the frequency of the occurrence of behavior (Shapiro, 1987). Typically, the observer records the number of times the behavior is observed within a specific time interval. The exact interval is kept constant throughout the observation period and can range from minutes to several days. Again, the time interval chosen is related to the specific type of behavior being observed as well as the availability of observation time and observers to collect the data.

Event recording is most successful when observing behavior that has a discrete beginning and ending. Throwing paper airplanes, the completion of a math problem, and the raising of one's hand are all examples of such behavior. Behaviors that are continuous or persist for longer durations are more difficult to observe using event recording. Examples of this type of behavior would be pencil tapping, talking out loud, or on-task behavior. For event recording to be used properly, an operational definition specifying the occurrence of each event is necessary. For example, an instance of pencil tapping may be considered to have ended after 10 continuous seconds of no pencil-tapping behavior. In this way, the frequency count for the behaviors actually represents the number of discontinuous instances of the behavior. Similarly, occurrences of talking out loud may be defined as ending after 30 seconds of silence. Although event recording is often used for such behavior, other methods more readily suited to nondiscrete types of behaviors are recommended and are discussed later.

The se of event recording is particularly helpful when observing low-rate behavior. Such behaviors often occur infrequently but are of interest because of their intensity or seriousness. For example, running out of the classroom may only occur once or twice a day but may represent significant difficulties for the student. In using event recording for such behaviors, the observer must be given specific definitions regarding the beginning and ending points of the behavior.

Behaviors that occur in response bursts are also good candidates for event recording. These behaviors usually occur in rapid succession with little or no discrete beginning or ending to each response. The entire set of responses is generally related to the same response class and thus can be counted as a single event. A good example of such behavior is aggression. A child who exhibits this class of behaviors may shout obscenities, hit other children, and then walk out of the classroom. Instead of counting each single behavior, the entire outburst can be defined as an aggressive incident. The observer must be instructed as to the dimension that designates the end of the outburst, for example, one aggression-free minute. Typically, response burst behaviors are of the low-frequency, high intensity type with the entire sequence of behavior counted as one single occurrence.

The methods for event recording are quite varied. Commonly, forms are provided for the observers on which the intervals are already delineated. Observers simply place a tally mark for the occurrence of each behavior (see Figure 1). However, other mechanical devices such as grocery store counters, golf wrist counters, and a wrist abacus can be used. Any device capable of keeping a frequency count can be used to perform event recording.

Duration recording. Another type of response that can be recorded is the duration of the behavior. The observer simply notes the length of time from the beginning of the response until it ends (Shapiro, 1987). For this measure to be useful, however, starting and finishing points of the behavior must be precisely defined.

Duration measures may be very helpful with certain types of school-related behaviors. Studying, temper tantrums, social isolation, and aggressive outbursts are good examples of responses in which the duration of the behavior is an important parameter. In each case, changing the duration of the response may in itself be the target for intervention.

Event and duration recording are usually combined to achieve effective assessment (Cooper, 1987). It is entirely possible with some behaviors that event or duration recording alone would not provide an accurate picture of the problem. If one child spends an entire play period and another, one 10-second observation interval in social isolation, both would be recorded as having a single occurrence of the behavior during the observation using event recording. The additional recording of duration, however, provides an accurate assessment of the difference between these students. Likewise, the recording of both frequency and duration may be quite important when examining study behavior. One student may be found to have numerous instances of study behavior all of a short duration, whereas another child may be found to have only a few instances of longer duration. In the former case, the goal for intervention would be to achieve more continuous instances of study behavior, whereas in the latter, to increase the frequency of studying. Finally, with disruptive behaviors, a child may have several very short disruptions each day whereas another child, one long, continuous disruption. By collecting both frequency and duration data, the target behavior for intervention can be precisely defined.

The most precise nonautomated instrument for duration recording is a stopwatch. A wall clock or wristwatch can also be used but will probably produce measures less precise than those obtained with a stopwatch. The procedure for recording total duration with a stopwatch is to start the stopwatch as the behavior begins and stop the timing at the end of the episode. Without resetting the stopwatch, the observer must start it again at the beginning of the second occurrence of the behavior and stop the timing at the end of the second episode. The observer continues to accumulate the durations of time in this fashion until the end of the observation period and then transfers the total duration of time showing on the stopwatch to a record sheet.

The procedure for recording duration per occurrence with a stopwatch is to start the stopwatch as the behavior begins and stop the timing at the end of the episode. The observer transfers the duration of time showing on the stopwatch to a data sheet and resets the watch. The stopwatch is started again at the beginning of the second occurrence of the behavior and is stopped at the end. The duration of time is again transferred to a data sheet and the procedure continued until the observation session ends. Figure 2 illustrates the use of a data sheet for recording duration per occurrence.

Latency recording. Latency recording is the measurement of elapsed time between the onset of a stimulus (e.g., verbal directive) and the initiation of a specified behavior (Cooper, 1987). Latency recording should be used when the major concern is the length of time between an opportunity to elicit a behavior (e.g., after the presentation of a verbal directive) and the actual time it takes to begin performing that behavior. The response latency would be the length of time between the end of the teacher's direction and the student's compliance. Concern also can focus on latencies that are too short. For example, a student may give incorrect answers because he or she does not wait for the teacher to complete the questions. The procedure for latency recording is similar to that for duration recording. Both report data on the temporal dimension of behavior, both use the same measurement procedure (e.g., use of some timing instrument such as a stopwatch), and both require precise definitions of the behavior to be recorded.

FIGURE 1. Example of frequency tally for hypothetical student. Instances of calling out, hitting, teacher approaches, and peer approaches are recorded during three time intervals.

BEHAVIORAL BASELINE

1 - 2	"	//		////	/

Time sampling. When behavioral observations are being collected, it is best if all instances of the behavior are recorded during the systematic observation periods. Unfortunately, practical concerns usually prevent this from being possible. Issues such as the availability of observers, the ability of the observer present in all settings in which the student interacts, and the lack of observer time to perform observations often prohibit continuous systematic observation. Unless the behavior is of low frequency, continuous event or duration recording is probably impossible. As a result, alternative methods of data collection must be employed.

In addition to the practical problems of continuous systematic observation, it is difficult to tell when some behaviors begin and end. Although event, duration, and latency recording can be used by precisely defining the parameters of the behavior, there are better and more useful methods for collecting data.

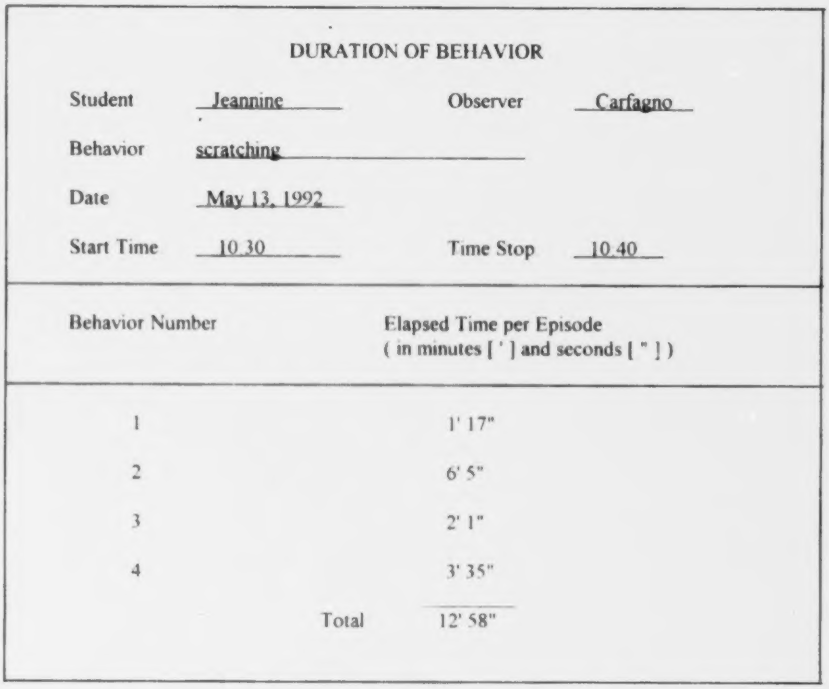
Time sampling is a technique that circumvents the difficulties just discussed. Instead of observing students continuously, the observation period is broken into a series of shorter timed intervals. Rather than record the frequency or duration, observers simply note whether the behavior occurred. From the recording of such data, an estimate of the actual frequency of behavior is obtained. When continuous observation is impossible, time sampling provides a method for collecting accurate and reliable data by only occasional observation. Similarly, with behaviors that are not discrete, time sampling allows the observer to make only a decision regarding the presence or absence of behavior, bypassing the problems of deciding whether it has begun or ended.

The use of time sampling represents one of the most frequently employed observation techniques in systematic observation. There exists a wide variety of ways in which time sampling can be performed.

When time-sampled data are collected, the entire observation period is divided into timed segments (Shapiro, 1987). The exact length of these segments varies according to the way in which the observation is being performed. For example, if an observer is able to sit in a classroom for a continuous amount of time, the intervals are usually short, around 10 to 60 seconds. If one is unable to perform continuous observations, the intervals may be lengthened to 30 to 60 minutes. Such long intervals may allow the teacher to collect the data with minimal intrusion on his or her instructional time. Likewise, if the behavior to be observed is of the high frequency, long duration type, short intervals may be more appropriate than the longer interval method. Regardless of the interval length, behavior is recorded as either present or absent. The various ways in which behavior is defined within the interval determines the type of recording procedure employed.

If a behavior is defined as present only when it occurs throughout a time interval, the *whole-interval* method of recording is being used. Such a definition requires the behavior to be evident from the beginning to the end of each interval or the interval would be scored as "behavior absent." For example, Ollendick, Shapiro, and Barrett (1982) in observing a child's appropriate block-play behavior in consecutive 10-second intervals, defined the behavior as "building towers or fences, making roads, and transporting blocks in trucks across the playroom" (p. 67). Children had to be engaged in this behavior for the entire 10-second period to be scored appropriate. Any instance of nonplay or inappropriate play resulted in the interval being scored as behavior absent. Although this technique could conceivably be used with long intervals, it is most applicable when short duration intervals are employed and to assess whether the behavior is continuous.

FIGURE 2. Sample data sheet for recording duration of behavior per occurrence.



DURATION OF BEHAVIOR

Student Jeannine Observer Carfagno

Behavior scratching

Date May 13, 1992

Start Time 10 30 Time Stop 10 40

Behavior Number	Elapsed Time per Episode (in minutes ['] and seconds ["])
1	1' 17"
2	6' 5"
3	2' 1"
4	3' 35"
Total	12' 58"

In contrast to whole interval recording, *partial interval* recording does not require the behavior to be present for the entire interval. Any single or multiple occurrences during the time interval will constitute that interval as being scored as behavior present (Shapiro, 1987). This procedure is particularly useful when recording noncontinuous behaviors that sporadically appear during the observation session.

Partial interval recording can also be helpful when using larger duration intervals. For example, a teacher may be asked to record throughout the day whether a particular student calls out. An easy method for time sampling this behavior would be to divide the day into 15-minute segments and have the teacher note if the behavior does or does not occur during each 15-minute period.

Another method of time sampling, called *momentary recording*, requires the observer to note whether a behavior is present or absent only during the moment when a timed interval begins (Shapiro, 1987). In this technique, the observer would not record any data regarding the period between intervals, only what was occurring during the instant of observation. For example, an observer asked to record the on-task behavior of a student would be using momentary recording if at the beginning of each 10-second interval they noted whether the student was on- or off-task at that instant. Like partial interval recording, this technique also can be used with longer duration intervals.

With any of the time sampling procedures, observers usually are provided with a form that has the intervals already marked sequentially. The type of form often used when making short interval, continuous observations is illustrated in Figure 3. An infinite variety of these forms exist and can include precoded behavioral categories or just blank space to record a "+" or "–".

Typically, observations of this type are done on an "observe-record" basis where a specified amount of time (usually 10–30 seconds) is allotted for observation and a shorter amount of time (5 seconds) to record the observation. In order to facilitate this process, the observer may use a small hand-held recorder with an earpiece in which a prerecorded tape specifies the beginning of each interval. It is recommended that prior to the observation this tape be made according to the interval specified, with prompts that cue the observer when and what interval to record (e.g., "observe 1," "observe 2," "observe 3," . . . "observe X"). Using such a system will provide a safeguard against "observer drift" and help ensure the correct recording of data.

FIGURE 3. Sample for conducting interval recording.

Reporting Data Collected

The purpose of direct systematic observation is the collection of data which can then be used for program planning and decision making. To accomplish this purpose, it is necessary to compare performance over time. What a student does at a specific point in time is usually not important for decision making or analysis if that performance cannot be compared to performance at other points in time.

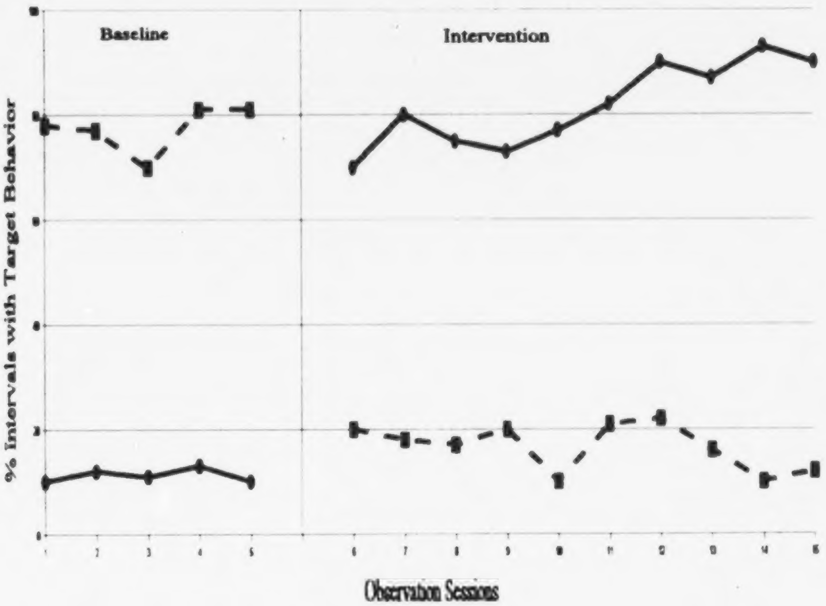
In addition, simply recording the amount of behavior is generally unacceptable. The amount of behavior should be converted to other units of measurement to allow for a comparison of behavior over time (Cooper, 1987). The major units of conversion are frequency, rate, and percentage measures.

Frequency of behavior. Frequency of behavior is the number of times a specific behavior occurs in some period of time (Cooper, 1987). Tallying, or counting, instances of behavior is possible when the behavior is readily observable and discrete. Frequency should be used only when time and opportunity for response are constant. If frequency measures are used without reference to these variables, overall performance is open to subjective interpretation. For example, frequency would be an appropriate measure if the student is consistently provided 30 math problems (the same opportunity to respond during each observation) to complete in 2 minutes (constant time during each observation). Frequency would not be appropriate if the number of problems varied from observation to observation, or if the amount of time to complete these problems varied from one observation to another.

Rate of behavior. Rate of behavior is a measure expressed as frequency per unit of time (usually per minute). Rate is calculated by dividing the total number of observed behaviors by the amount of time spent producing those behaviors (in minutes) and multiplying by 60 (due to the fact that there are 60 seconds in a minute). Rate of response is considered the basic datum of the science of behavior (Skinner, 1966).

Percentage of behavior. Percentage of behavior is a ratio that expresses the amount of a behavior as a certain number of responses per every 100 opportunities. Percentage is obtained by dividing the total opportunities for a specific behavior (e.g., 50 intervals) into the number of times the behavior was actually observed (e.g., the specific behavior was observed in 10 of those intervals) and multiplying that result by 100 (10/50 = .20 x 100 = 20%).

FIGURE 4. Use of a line graph on which two behaviors are monitored concurrently.



Graphic Display of the Data

The line graph is the most commonly used graphic display for presenting daily data. Figure 4 shows a simple line graph on which tow behaviors (academically engaged and off-task) are concurrently monitored across time.

The line graph has several advantages, the most important being that it is familiar to, and therefore easily understood by most teachers. In addition, it is easy to construct and permits the school psychologist and teacher to evaluate continuously the effect an intervention has on the target behavior, thus facilitating formative evaluation and the decision to maintain or modify the intervention (Tawney & Gast, 1984).

SUMMARY

Significant effort has been made over the last decade in shifting the role of the school psychologist toward a problem solver rather than a problem identifier. To problem solve successfully, school psychologists must have methodologies that match this function. Systematic observation provides one of the most useful assessment strategies to accomplish this goal. Its emphasis on the links between assessment and intervention are clear. It remains focused on identifying socially valid and meaningful behavior change. Additionally, systematic observation provides a means for psychologists to be highly accountable for their recommendations and to offer direct feedback to teachers regarding the effectiveness of these recommendations. Further, the emphasis in systematic observation on data collection under the conditions and in the setting where the problem behavior has arisen places the psychologist in close contact with the teacher's perspective of the problem.

Like any new skill, use of systematic observation will take time to learn. School psychologists should not be fooled by its apparent simplicity; it is wise to devote as much time in training to the use of these strategies as is typically devoted to learning a newly published, standardized norm-referenced test of intelligence. With continued use, however, school psychologists will find systematic observation to be an important and crucial asset to the services they can offer on behalf of helping teachers work better with children.

Best Practices in Individualized Education Programs

Nancy A. McKellar
Wichita State University

OVERVIEW

The individualized education program (IEP) is the legally prescribed mechanism for designing and monitoring student-specific education and is required for all students receiving special education services. Kaye and Aserlind (1979) have proposed that the IEP should be considered as both a product and a process.

The elements that must be included in the written product are specified in the rules and regulations (U.S. Office of Education, 1977) that govern the implementation of the Education for All Handicapped Children Act of 1975 (Public Law 94-142). These elements include the student's present levels of educational performance; annual goals and short-term instructional objectives; specific special education and related services; extent of the student's participation in regular education programs; initial dates and duration of services; and criteria, procedures, and schedules for evaluating attainment of the short-term objectives. This document must be reviewed and revised at least annually. A sample abbreviated IEP is available in *Best Practices–II* (McKellar, 1990).

When the federal law was amended in 1990 and renamed the Individuals with Disabilities Act (IDEA; Public Law 101-476), a new requirement was added. No later than when the student is 16 years old, the IEP and each revision of it thereafter must include a statement of the transition services needed by the student upon leaving school and entering adult life.

The IEP document reflects the decisions made by a team of persons who are important to the student's education. Legally, the team must include the student's teacher (regular education teacher for a student who has not been receiving special education services and special education teacher for students who have); an administrator with authority to commit the educational agency's resources to implement the IEP; and one or both parents. The student and other persons may be included on the team at the discretion of the parent(s) or the agency. Also, one of the persons who conducted the comprehensive evaluation or someone knowledgeable about the evaluation and the results must be included on the IEP team the first time the student is evaluated.

The history of treatment of the IEP in the professional literature has been described as consisting of three major phases (Smith, 1990b). In the first phase, many authors described and explained the IEP norms and standards. In the next phase, researchers focused on the process of developing the IEP document. The final phase is one in which efforts have been made to manage IEP document development with computer-assisted systems.

Hopefully, the next phase will be one in which the relevance of the IEP to improving students' educational experiences is emphasized. The IEP is the logical link between assessment and intervention. Also, many states are considering and implementing outcomes-based education for all students. The short-term objectives and annual goals of the IEP represent the expected educational outcomes for the student receiving special education services.

School psychologists are likely to be the only experts in measurement on the IEP team. Also, they are trained in many of the skills that are required for problem-solving groups such as IEP teams to function effectively. These skills include knowledge of team strategies, problem-solving skills, and interpersonal factors (Zins, Curtis, Graden, & Ponti, 1988). School psychologists can help other team members to develop the IEP by assisting with integrating the data, planning the individualized program, and promoting generalization and maintenance of skills. This role is consistent with ethical standards for school psychologists (National Association of School Psychologists, 1992; see principles in Section IV.B.).

BASIC CONSIDERATIONS

Problems with the Product

Research has shown that the IEP is not always a working document that guides the student's educational program. Lytle (1992) reported that the majority of special education teachers who were studied in

Philadelphia found the IEPs of students entering their classrooms of "little or no value in planning instruction" (p. 192). Dudley-Marley (1985) studied teachers who said that IEPs were seldom referred to and often were locked away or otherwise not readily accessible to them.

To become more useful to teachers, the IEP should build on information about the student gained in the comprehensive evaluation. If the assessment procedures have included a consideration of the conditions under which the student learns best, and not just focused on special education eligibility issues, then the recommendations from the assessment should be reflected in IEP goals. However, Fiedler and Knight (1986) reported that only 0–25% of diagnostic recommendations are translated into IEP goals. In a study of the IEPs of male elementary school students with behavior disorders or learning disabilities, Smith (1990a) found that only 62% of the time was there a match between an identified need of the student and an annual goal.

Another problem with IEP documents is that they are sometimes not uniquely geared to the individual student. If the IEP represents a program that truly is individualized for the student, then IEPs should differ from one another to the extent that students differ from one another in their educational needs. When Nutter, Algozzine, and Lue (1982) compared IEPs for students within the same disability areas, they did not find significant differences. In *Board of Education v. Rowley* (1982), the U.S. Supreme Court included in the criteria for appropriate education of students with disabilities the existence of an IEP that is "reasonably calculated to enable the child to receive educational benefits" (p. 207). If IEPs are not blueprints for individually designed instruction, the appropriateness of the education received by the students is suspect (Smith, 1990b).

Problems with the Process

Parents, regular education teachers, and other persons with information relevant to designing student-specific education do not always attend and/or fully participate in the IEP conference. In the Collaborative Study of Children with Special Needs (Silverstein, 1988), five large metropolitan school districts throughout the United States were studied for over 5 years. Less than half the parents attended their child's IEP meeting. The reasons for the low parental involvement were varied, including intimidation of parents by the process, scheduling conflicts, lack of childcare, and burnout from parenting a handicapped child.

Attendance by the school psychologist at IEP meetings appears to vary considerably, according to such factors as geographic location and district policy. In a study of initial IEP planning conferences for mildly handicapped children in five North Carolina school districts (Vacc et al., 1985), only 13% of the meetings were attended by all the persons required in the federal guidelines. Those typically absent from the meeting were the local education agency representative and a professional, such as the school psychologist, who was qualified to interpret assessment data. In contrast, Vaughn, Bos, Harrell, and Lasky (1988) found that the school psychologist attended all of the initial placement/IEP meetings for students suspected of having learning disabilities in a large southwestern school district.

The participation among those at the IEP conference typically varies, with parents and regular education teachers participating less and in more passive ways than special education teachers (Vacc et al., 1985). These inequalities in participation may be influenced by the practice of writing the IEP document prior to the actual meeting. Parents feel that they are being presented with decisions rather than recommendations for a plan to which they also can provide input (Gartner & Lipsky, 1992). Also, parents' incomplete understanding of their child's handicapping conditions and the nature of the decisions to be made during the conference may contribute to parents' sparse, passive participation (Vaughn et al., 1988).

Parents can be caught in a no-win situation (Gartner & Lipsky, 1992). On the one hand, if they complain that their child is not receiving adequate educational or related services, the school personnel may respond by stereotyping the parents as overprotective. If the parents, for whatever reason, have less time to be involved in their child's education and/or therapy, then they may be labeled as in denial In both of these views of parents, they are seen as being part of the problem rather than a valuable resource who can provide knowledge about the student and support for the educational program.

Vaughn and her colleagues (1988) found that some parents expressed uncertainty about how to explain to their child the learning problem and the planned changes in the child's educational program. The law allows the student to attend the IEP conference but this rarely happens.

A final problem with the IEP process is that plans for implementation and for integrating students into the regular classroom are discussed very little at IEP conferences (Vacc et al., 1985). Perhaps that is why so little correspondence has been found between the content of the IEP and the observed instructional activities in which the student engages (Lynch & Beare, 1990). Information on what to do once the IEP document is prepared, signed, and filed is noticeably lacking in the IEP literature. Methods of monitoring and evaluating the interventions prescribed in the IEP document have not received sufficient attention. It is only by completing the problem-solving process that the IEP can be instrumental in students' attainment of their educational goals.

BEST PRACTICES IN INDIVIDUALIZED EDUCATION PROGRAMS

Improving the Product

Important decisions for the IEP team have to do with which behaviors, set to what criteria levels, are to be described by the goals. When selecting the behaviors for improvement, the IEP team should consider those behaviors that are most central to the student's education. Such diverse behaviors as decoding unfamiliar words, feeding oneself with a spoon, and expressing one's anger in appropriate language might be included. Typically, the behaviors identified in the IEP goals will be ones in which the student is most discrepant in comparison with nondisabled peers. Norm-referenced comparisons will be required to make such judgments.

Criterion-referenced comparisons also could be the basis of goal selection. Skills that the student performs at the independent level would be considered an academic or social strength. In contrast, a skill on which the student performs no higher than the instructional level, or with 80% success, might be considered a weakness that should be the basis of an IEP goal.

In general, the annual goal represents the amount of progress that the IEP team expects the student to make in a single year. The author has asked teachers, in both special and regular education, how the IEP teams on which they serve determine how much progress it is reasonable to expect of a special education student in the time span for which the IEP is written. A common response has been, "It's a mystery to me." One option for the goal is that the student acquire a specific skill. This option requires the team to define the skill in such a way that it is clear to all what success looks like when it occurs. The goal could be that the student simply show any improvement. In this case, the team only needs to know the student's current level of performance.

Several other options for defining the expected improvement require information about the performance of the student's regular education peers (Fuchs & Shinn, 1989; Shinn, 1986). One option is to expect the special education student to catch up with regular education peers by reaching grade level performance. This criterion level is unrealistic because it means that the student will have to progress at a faster rate than the other students. Keep in mind that this expectation would be placed on a student who by virtue of his/her eligibility for special education has been recognized already as progressing at a rate less than her or his peers. Another option for the level of improvement expected of the special education student is to maintain the same rate of improvement as the nondisabled peers. This standard would keep the student at the same relative position with respect to the peers. McKellar and Jeffrey (1993) have proposed that improvement relative to one's own previous rate of progress could be considered a reasonable goal for a student. This approach requires that data on the student's rate of previous change be used by the IEP team in establishing the criterion level. Teams should be cautioned against "playing it safe" by setting goals low, because goal ambitiousness has been shown to be positively correlated with students' achievement (Fuchs, Fuchs, & Deno, 1985).

Implicit in the development of the goals is a comparison of the student's current performance with the desired performance represented by the goal. A determination needs to be made as to whether the student cannot or will not perform the desired behavior at this time. It can be helpful to ask, "Has anyone observed the student performing the desired behavior at any time under any conditions?" If the answer is yes to this question, then the focus of the intervention should be on getting the student to perform the behavior when and where desired. This approach has a performance focus for addressing a "won't do" problem. If the answer to the question is no, then a skill deficit may exist and the student "can't do" the desired behavior at the present time. Task analysis can reveal any prerequisite skills that need to be taught to move the student toward goal attainment.

The short-term behavioral objectives related to each goal on the IEP represent steps for dealing with a performance or a skill deficit. Suppose that the goal is for the student to add two-digit numbers. If an examination of the student's current behavior reveals that he or she performs this behavior correctly when given only this type of problem and not a sheet with several types of problems, then the short-term objectives might represent a series of steps to shape the student to perform the goal under more varied conditions. On the other hand, if error analysis reveals that the student does not regroup correctly, then the short-term objectives might represent skill instruction in place value and the algorithm of regrouping.

Weisenfeld (1986) recommends that the IEP contain no more than 10 annual goals, with fewer being appropriate for many students. Once the goals are selected, task analysis and error analysis are required to determine the student's current skills and knowledge in the areas addressed by the goals and to identify and sequence the objectives needed to achieve each goal. The short-term objectives should be written as behavioral objectives. The use of specific behavioral descriptions is important so that there is no misunderstanding of the skill to be achieved and the behavior can be measured.

One consideration in selecting the objectives for a student is whether the programming represents active or passive instruction. Downing (1988) defined active IEP objectives as those "that specify behaviors/skills the student is expected to acquire upon completion of instruction" and passive IEP objectives as those "that state what staff will do to student . . . and/or provide general information on what activities will be provided" (p. 198). Active programming has been shown to improve the likelihood that students with severe disabilities will participate in their environments in functional, age-appropriate activities. Care must be taken to insure that IEP objectives for these students are age-appropriate and functional and represent active, rather than passive, instruction.

A critical component of the short-term objectives is the criterion level included in each. As a general rule, the criterion should not be set at 100% accuracy. With the exception of behaviors related to safety, there is no need to have that high a level of performance. Setting a criterion of 100% ensures failure to reach the objective. Instead, set the criterion level so that the student will have sufficient competency on that objective for it to be a realized prerequisite skill in the attainment of more advanced objectives.

Improving the Process

The development, implementation, and evaluation of the IEP are part of the overall problem-solving process that is required to provide education that meets the needs of students with disabilities. The problem-solving process can be enhanced by the school psychologists' use of good consultation skills (McKellar, 1991). These skills include actively listening to the concerns of parents, teachers, and other IEP team members. It may be necessary to help other team members understand the role of the school psychologist in the IEP process and also the limits of confidentiality in the consultation relationship. School psychologists should be familiar with the empirically demonstrated effectiveness of different interventions so they can assist the teacher in selecting the methods to use to move the student toward attainment of the IEP goals.

IEP team members should become aware of other members' competencies and their relationship to IEP development. The differing perspectives of group members may help bring about a solution for the targeted problem. Written policy statements on the responsibilities of the team members during IEP development, implementation, and evaluation are recommended. The process of IEP development can be improved by providing IEP team members with training in decision making (Poland, Thurlow, Ysseldyke, & Mirkin, 1982) and in how to use the competencies of each team member to enhance IEP development (McKellar, 1991).

The fact that some districts have rates of parent attendance at IEP meetings as high as 95% (Singer & Butler, 1992) indicates that it is possible to develop formats for IEP meetings that are parent-friendly. Special attention should be given to ways of helping parents and teachers participate as partners equal to administrators and support personnel in the IEP process. Parents and teachers usually lack formal training in problem solving or consultation (McKellar, 1991). They can be provided with a brochure prior to the IEP development meeting that gives the agenda, the meeting participants, and the role that each, including parents and teachers, will be asked to take. They can be helped to prepare for the IEP meeting with a written outline of the discussion topics and important decisions, on which space has been left between items for questions that they might want to ask. At all meetings the discussions and written materials should be free of educational jargon. Those who participate on the IEP team less infrequently, as is the case with parents and regular education teachers, should be given the name and telephone number of another IEP team member who can provide clarifications and answer questions before and after the meeting.

Determining the student's needs should occur at the beginning of the problem-solving process as part of identifying and clarifying the presenting problem, a crucial step in successful problem resolution (Bergan & Tombari, 1976). Whether the problem is attributed to factors internal to or external to the child affects expectations about whether the interventions are likely to succeed (Zins et al., 1988). The way in which the problem is defined will determine which interventions are selected. A useful technique in identifying the problem is to discuss the specific behaviors of concern that the student is exhibiting. This discussion can lead to a separation between what the student actually is doing and the meanings that different team members may be attributing to the behavior.

An important topic to discuss at the IEP meeting is how the results will be communicated to the student. This explanation will help students make adjustments to the planned changes more easily. A preferable procedure is to include the student in the IEP problem-solving process whenever possible, in order to increase the student's commitment to the interventions selected (Maher & Yoshida, 1985). Peters (1990) has provided specific suggestions for facilitating student involvement in each phase of the IEP process. For example, students can be asked to share their likes and dislikes, and this information can be used to determine present and potential reinforcers. Also, prior to the IEP meeting the student can role-play with another team member the appropriate and expected behaviors to use at the conference.

IEPs can impact the students for which they are written only when they are implemented. The specific interventions that will be used to move the student to attainment of the IEP goals are not part of the IEP document. The interventions that are considered can be ones aimed at changes in the environment as well as changes in the student. The persons who have the most relevant information about the student's functioning and/or who will implement the interventions required to achieve the goals in the IEP need to participate in the IEP planning meeting. Incorporating the ideas of parents and teachers into the intervention plans increases their commitment to carrying out the plans. Providing a consultant to help teachers incorporate instruction related to students' IEP objectives into the existing classroom program results in concomitant increases in attainment of the IEP objectives (Peck, Killen, & Baumgart, 1989).

The means for evaluating the attainment of the IEP goals and objectives are a required part of the IEP document. For example, if the IEP objective is that Mary will read aloud correctly 90% of the words from a specified word list, then the objective should be evaluated by having Mary read the word list and computing the accuracy of her performance. Curriculum-based assessment, performance assessment, and portfolio assessment are among the assessment approaches that are particularly well suited to monitoring students' performance. The evaluation process with these methods is ongoing.

The system that will be used for monitoring progress in attaining the objectives should be discussed at the time that the IEP is developed. Ongoing data collection is essential to the IEP monitoring process. An effective practice is to graph the data so that change is apparent visually. An aimline can be drawn from the student's beginning level of performance at the left of the graph to the criterion performance at the right, to signify the rate of progress necessary to reach the goal. If the student's performance as the interventions are implemented is lower than the aimline, either the criterion level of the goal or the intervention being used will need to be changed. The former requires the approval of the IEP team. Before giving up on the planned criterion, however, it is probably best to change or alter the intervention. Error analysis of skill performance and functional analysis of behavioral sequences can be very useful at this point in identifying how or what to change with respect to the intervention. It is important, however, not to continue to do something that the data show is not working. Howell, Fox, and Morehead (1993) present a lengthy table relating possible decisions on how to change an intervention to the data that would support each specific change. Without ongoing data collection during the implementation of the interventions for reaching the IEP goals and objectives, it may not be readily apparent that an intervention is not working as expected until much of the student's valuable educational time has passed.

Rosenfield (1987) advises that teachers should be expected to adapt interventions to fit the situation. An important role of the school psychologist consultant is to assist and support teachers while guarding the integrity of the interventions. This requires frequent contact between the consultant and the teacher, whether in person or by telephone. Since this type of support is vital to the intervention's success, the IEP development meeting should include a discussion of who will implement the various interventions and who will act as the consultant.

If short-term objectives are being met, even if somewhat off schedule from the timetable listed in the IEP, the intervention process probably should continue. If the persons implementing the interventions find it necessary to add or delete objectives, such a change in the IEP must have the approval of the IEP team.

SUMMARY

The IEP is the means required by law for designing education for students with disabilities that is "special," meaning that it is uniquely appropriate to the student's needs. Much has been written about the form of the IEP document and the basic steps in developing the IEP. In this chapter, emphasis is on some of the more difficult issues faced by IEP teams in selecting the behaviors targeted for improvement, setting the criterion levels of the short-term objectives, and determining how much progress to expect of the student during the period covered by the IEP. Also presented are practical suggestions for improving the problem-solving process through more meaningful participation by all IEP team members, careful problem identification, and the monitoring, adjustment, and evaluation of resultant interventions. Only when the problem-solving process is completed with successful interventions is the student's education impacted positively by the IEP as Congress intended.

This book is intended to help teachers make educational decisions about what to teach and how to teach. The first decision, what to teach, underlies much of the IEP team's work. The second decision, how to teach, must be made by the teacher in order to implement the IEP.

Ortiz, A. A., & Yates, J. R. (1989). Staffing and the development of Individualized Education Programs for the bilingual exceptional student. In L. M. Baca & H. T. Cervantes (Eds.), *The bilingual special education interface* (2nd ed.; pp. 183–203). St. Louis: Mosley.
As our nation becomes increasingly multilingual, more school psychologists will be participating on IEP teams that are making decisions about the educational programs of bilingual exceptional students. The special considerations in developing and implementing IEPs for these students and in working with their families are discussed in this chapter.

Rosenfield, S. A. (1987). *Instructional consultation*. Hillsdale, NJ: Erlbaum.
Good consultation skills are required by the school psychologist to assist in the development, implementation, and evaluation of the IEP. This book contains many practical suggestions for the consultant, particularly when selecting and implementing interventions.

Shore, K. (1986). *The special education handbook: A comprehensive guide for parents and educators*. New York: Teachers College Press.
The special education process, including the IEP document and its development, is explained by a school psychologist in a clear and well-organized manner. Specific suggestions are offered to enable parents to become more active contributors to their child's individualized education program.

Zins, J. E., Curtis, M. J., Graden, J. L., & Ponti, C. R. (1988). *Helping students succeed in the regular classroom: A guide for developing intervention assistance programs*. San Francisco: Jossey-Bass.
Many practical suggestions are offered for working with teachers in a problem-solving process to assist students. The orientation is toward teacher assistance teams working in regular education, but the process is also applicable to the IEP development, implementation, and evaluation sequence.

Best Practices in Collaborative Problem Solving for Intervention Design

Sarah J. Allen
Janet L. Graden
University of Cincinnati

OVERVIEW

This chapter describes a *process* that can guide assessment and intervention procedures used in addressing academic and behavior concerns of students. The primary focus is on the two basic components of the term *collaborative problem solving. Collaborative* refers to the nature of the relationship between the participants in problem solving, the teacher(s), parent(s), student, and the school psychologist, who are *equal participants* in the process. *Problem solving* refers to the *systematic approach* used to conceptualize a problem situation, identify needs, design strategies to meet those needs, and implement and evaluate the strategies. Moreover, collaborative problem solving describes a way for school psychologists to organize their approach to service delivery — assessment and intervention, consultation for systems-level concerns such as school-wide discipline and school crises, counseling, and program planning and evaluation. Collaborative problem solving, with a foundation in consultation as a services delivery approach, has been long described in the school psychology literature as an effective and efficient way of providing services because it aims to help more students, focuses on *solving* problems in direct ways, involves relevant individuals in the intervention planning, and ultimately, enhances classroom and school situations for students.

Collaborative problem solving as a model for organizing services delivery has taken on renewed importance with the growing concerns about special education and increasing application of general education reforms in assessment and instructional approaches. Now, more than ever before, educators and parents are looking for ways to more directly assess student learning and performance (e.g., authentic assessment, performance-based assessment, outcome assessment). Parents of children with disabilities are seeking assessment that focuses more on describing specific skill, intervention, and support needs rather than on documenting deficits for the purposes of accessing services (e.g., Ahearn, 1993). Educators, in both general and special education, are desiring instructional, behavioral, and social-support approaches that meet the needs of *all* learners and accommodate the diversity existing among learners in all classrooms (e.g., Roach, 1992).

As a method for systematically approaching assessment and intervention design, collaborative problem solving also represents a useful way for school psychologists to rethink and reconceptualize their own approach to service delivery and the ways they can address these and other needs of students and teachers. By using a systematic approach in collaboration with others to clearly identify concerns, analyze and evaluate the factors affecting the concern, and design and evaluate specific interventions intended to remediate or eliminate the problem situation, school psychologists can provide an underlying framework for addressing the many different problems occurring in schools today, potentially at any of several levels within the organization.

In a time when students are experiencing more disturbing problems and facing increasing challenges and schools are struggling to meet diverse needs with sometimes fewer resources, school psychologists can be seen as vital when they help to address the problems of students and teachers. This will require a shift from the perception of school psychologists functioning to diagnose and assess problems to being seen more as a problem-solving facilitator and participant. However, the national context is conducive to such a shift. Major national reports and policy reviews have advocated for such changes (e.g., National Association of School Psychologists, 1994; Roach, 1992) and some states have already begun to systematically reform services delivery to more of a problem-solving and intervention focus (e.g., Iowa, Pennsylvania, Ohio).

BASIC CONSIDERATIONS

Collaborative problem solving as a framework for approaching problem situations has its foundations in many interrelated literatures in school psychology,

psychology, education, and special education. Among its key foundations are the scientist-practitioner approach; ecological and behavioral approaches to conceptualizing problems, assessing, and intervening; and consultation.

Scientist-Practitioner Approach

In the scientist-practitioner approach to psychological services delivery (described in detail in Barlow, Hayes, & Nelson, 1984), the practitioner relies on theory and research to guide assessment and intervention decisions, and intervention choices are treated as testable hypotheses. In this framework, all assessment is linked *directly* to intervention — assessment serves the purpose of gathering information to answer specific questions to inform intervention choices. One specific method for guiding this question-driven, hypothesis-testing process linking assessment to intervention, the Referral Question Consultation Method (RQC), is described in more detail in Batsche and Knoff (this volume). Interventions are selected based on determining (a) the most supportable hypotheses and (b) those predictions regarding interventions judged to have potential for success, based on prior research or founded in theoretical conceptions.

Another important feature is that interventions, as testable hypotheses, must be systematically monitored to assess whether they produce desired outcomes. Thus, informed decision making, question-focused assessment, a rationale for intervention selection, and a reliance on systematic data collection to monitor intervention outcomes are central features of a problem-solving approach to intervention design premised on a scientist-practitioner model.

Behavioral and Ecological Foundations

Although a generic problem-solving approach to child-related problems is not linked solely to behavioral and ecological foundations, behavioral and ecological approaches to assessment and intervention planning provide a strong, direct foundation for problem solving. Behavioral approaches stress the importance of

- Specifically defining and clarifying concerns.
- Analyzing both contexts in which behaviors occur and variables that are hypothesized to effect, control, and reinforce the behavior.
- *Directly* (versus indirectly) assessing the behaviors of concern in relevant environments.
- Intervening directly and in relevant environments.
- Directly assessing intervention outcomes.

This approach can be contrasted with, for example, a diagnostic-prescriptive approach in which the focus is on assessing to determine a diagnostic label or category (e.g., learning disability, attention deficit disorder) that leads to a general prescription presumed to be related to the label. In contrast, a behavioral approach focuses on specific behaviors, skills, deficits, excesses, and environmental supports needed to enhance skills and support desired behaviors and performance. Also, in a behavioral model, the individual (within specific environments) is the level of analysis, whereas in other assessment approaches, there is more emphasis on normative comparisons and descriptions. Knutson and Shinn (1991), Lentz and Shapiro (1986), and Shapiro (1989) all include more detailed descriptions of behavioral foundations of problem solving.

Obviously, behavioral approaches include an examination of the context in which behaviors occur and therefore are ecological in nature. A problem-solving approach relies heavily on this ecological foundation in recognizing the importance of systematically and directly assessing *contexts* and including these contextual variables, not primarily child deficits, in the intervention plan. By emphasizing a problem *situation*, the ecological approach moves away from a primary emphasis on a problem as child focused and toward an understanding of a behavior or situation in a context. Major features of an ecological approach are described in more detail in Conoley and Conoley (1992) and Haynes (1992).

Consultation

Consultation has long been promoted as a way to organize service delivery and to assist teachers and parents to develop interventions for children. The consultation literature includes descriptions of several consultation models (e.g., behavioral consultation, Bergan, 1977; Bergan & Kratochwill, 1990; mental health consultation, Caplan, 1963; Meyers, Parsons, & Martin, 1979; collaborative consultation, Conoley & Conoley, 1982; Idol & West, 1987; collaborative problem-solving consultation, Gutkin & Curtis, 1990). However, as described in major consultation texts (e.g., Brown, Pryzwansky, & Schulte, 1987), these various approaches for organizing and describing consultation share many common characteristics. All emphasize, to some extent, relationship building and interpersonal variables, including developing a collaborative relationship. All also use a systematic approach to problem solving that involves the basic steps of problem identification, analysis of relevant features affecting the problem situation, intervention planning and development, and evaluation of progress toward desired outcomes.

Although the consultation literature was used heavily for the framework of this chapter, this chapter's authors have come to prefer the term *collaborative problem solving* to *consultation*. It seems to us that the former term

- Is more descriptive of what actually occurs in the consultative process.
- Emphasizes the collaborative nature of the problem solving across all phases.
- Avoids some terms used in the consultation literature (e.g., consultant, consultee) that by their very nature imply an expert/recipient model, with the consultant being the expert and the teacher or parent being the more passive recipient of the process.

In collaborative problem solving as described here, all participants engage actively in the process and share power in decision making. The notion of mutual problem solving, shared power, and active engagement in the process have been described as critical components of problem solving by others (e.g., Gutkin & Curtis, 1990), so this is not a novel idea. However, this chapter emphasizes and describes the process very specifically throughout the ensuing sections on problem solving.

ASSUMPTIONS UNDERLYING THE PROBLEM-SOLVING APPROACH

Careful consideration of the features of a collaborative problem-solving approach to intervention design reveals a number of assumptions that underlie this model of service delivery, both in theory and in practice. Practitioners adopting this approach to intervention design will find that endorsing these basic assumptions is prerequisite.

All Children Can Learn

A guiding principle of the National Association of School Psychologists (NASP) review of policy and practices regarding assessment and eligibility in special education is the premise that "all children can learn" (NASP, 1994, p. 2). Some children learn faster or slower, and some learn best differently than others. However, all children have the potential to learn. Further, federal legislation dictates that all children have a right to a free and appropriate education regardless of categorical label. As a result, it is incumbent upon education systems and school professionals to deliver services responsive to the needs of all children — with and without disabilities.

The implication of this assumption for a problem-solving approach is that it becomes the task of problem solving and the responsibility of the problem solvers to discover the interventions and supports that will enable children to learn. In this view, identification of a deficit or a need is only the first step in problem solving, not a goal in itself.

Learning is an *Interaction* Between Learner and Environment

Also underlying a collaborative problem-solving approach to intervention design is the premise that learning and behavior problems are a result of an *interaction* between a particular learner and his or her environment. The focus is on identifying a child's *needs* and the environmental *supports* required to meet those needs. This is fundamentally different from an internal child attribution, deficit-focused approach that underlies the current categorical model. A focus on interactions between learner and the environment has obvious implications for assessment in a problem-solving model. In this approach, assessment is focused on both learner characteristics and environmental variables as they affect the learner, skills, and performance. Environmental factors such as classroom features, instructional methods used, task demands, and responses and reinforcers are systematically assessed for the purpose of designing interventions that modify environmental variables.

Assessment and Intervention Must be Multidimensional

This principle stems logically from the person–environment interaction. Because learning is the result of an interaction between a learner and his or her environment, any procedures aimed at understanding that situation must be multidimensional and include consideration of both the learner and the environmental context and the interaction between them. Although the nature of and procedures for collecting data will depend upon the characteristics of each problem situation, some of the critical variables that need to be addressed include

1. Child variables, such as current skills and behaviors (e.g., academic, social), performance versus skill deficits, competing behaviors, response style.
2. Curricular variables, such as scope and sequences of objectives, placement versus expected placement in curriculum.
3. Instructional variables, such as teaching strategies, opportunity to respond, practice time, contingencies both during and after work is completed, feedback procedures.
4. Classroom context, such as class size, physical arrangement and structure, equipment, materials, and other resources available.
5. Peer intervention and support.
6. Teacher interaction, such as teaching strategies, classroom management strategies, instruction giving, and feedback format.
7. School and/or district variables, such as policies and resources available.

8. Family variables, such as support systems, stressors, interactions, and parenting skills.

9. Community variables.

More detailed descriptions of the focus and procedures of multidimensional assessment for intervention design are available in Lentz and Shapiro (1986) and Shapiro (1989).

Problem *Solving*, not Problem Finding, Sorting, Labeling, or Admiring

All too often the delivery of services to children with needs gets stalled at the point of "admiring the problem" (see footnote); that is, focusing on student deficits rather than solving the problem through specific interventions. Considerable time and energy can be devoted to assessing and diagnosing a problem for the purpose of determining a categorical label. However, with a primary focus on determining *what* the problem is or which label the child is eligible for, little or no time is spent in designing, implementing, and evaluating interventions to provide supports for student needs. In contrast, the primary purpose of the collaborative problem-solving approach to service delivery is to identify and provide the support, services, and/or accommodations needed to resolve the current problem situation.

Needs-Based, not Eligibility-Driven Model

A problem-solving approach to service delivery urges that for specific needs of children, rather than categorical labels with questionable implications for intervention, serve as the basis for design and delivery of supports and services. This conceptualization of the term *problem solving* focuses not on problems or deficits within and belonging only to children (NASP, 1993/94), but rather on addressing children's needs, which may include needs for improved competence in children as well as needs for environmental or instructional modifications.

Assessment and Intervention: Necessarily Idiosyncratic

Assessment refers to a process of gathering information needed to answer questions about a specific problem situation. Information derived from the assessment process should form the basis of intervention design. Based on the unique characteristics, experiences, and needs of each child and the distinctive nature of the environmental context in which each problem situation is occurring, both assessment and intervention are necessarily idiosyncratic. Throughout each phase of problem solving, the focus should remain on situation-specific solutions to situation-specific problems.

IMPORTANT ASPECTS OF PROBLEM SOLVING

Collaboration

An important aspect of the problem-solving approach to service delivery is collaboration among all participants (e.g., professionals and parents) at every step in the process. Unlike the medical model of service delivery in which the person functioning in the role of consultant is regarded as an "expert" who will dominate decision making, the problem-solving approach assumes that the knowledge and expertise of all participants are essential in the development and implementation of effective intervention strategies. As a result, parents, teachers, principals, school psychologists, and others must work together to clearly understand identified concerns. Giving consideration to both individual (e.g., student, teacher) and situational (e.g., classroom, school, community) variables that may affect performance, responsibility for planning and implementing interventions also are shared by all participants. Ultimately, however, final decision-making power regarding selection of intervention strategies is given to the person(s) assuming responsibility for implementation. Lastly, evaluating outcomes and considering needed modifications are also cooperative efforts.

Multilevel Service Delivery System for Problem Solving

Reflecting the need for and availability of support, efforts to intervene with student-related problem situations can occur at different levels within the school organization. Curtis, Curtis, and Graden (1988) provided a framework for conceptualizing the implementation of problem-solving efforts within a multilevel service delivery system resembling a pyramid.

Personal problem solving. Initially, teachers attempt to intervene with student-related problem situations through personal problem-solving efforts. In recognition of that fact, the first level of service delivery depicted on the Figure 1 pyramid involves classroom teachers collaborating in problem solving with another teacher. At this level, problem-solving steps and activities (e.g., delineating plans, monitoring changes) tend to be informal and unstructured.

One-to-one problem solving. At the next pyramid level, classroom teachers engage in collaborative problem solving through one-to-one consultation with individual special services personnel. Adhering to a systematic approach to problem-solving steps, Curtis et al. (1988) recommended that specific intervention plans be recorded and outcome data be monitored.

Group problem solving. Within this multilevel system, the highest level of service delivery is repre-

sented by group problem solving. The composition and function of the group may vary, such that all members of the group may problem solve as a team, or the group could engage in problem clarification and then assign one member as a collaborator to assist the teacher. Certainly group problem solving is the most costly configuration of these service delivery options in terms of personnel time and resources and, therefore, is best used only to address the most complex and difficult problem situations.

Data-Based Decision Making

Finally, data-based decision making is an important aspect of collaborative problem solving. In fact, at each phase of the problem-solving process, assessment data generated from direct measures relevant to the problem situation form the basis for making decisions about the subsequent course(s) for action. For example, rather than making comparisons with a normative reference group, data generated from direct measures and tools is used to set goals and monitor progress toward attaining desired behavior relative to this problem situation. Further, brief, repeated measures of progress towards these goals are used to evaluate the success of interventions and to determine the need to change interventions when they are not resulting in the desired progress toward goals.

BEST PRACTICES/ PROBLEM-SOLVING STEPS

Although the literature includes descriptions of many different models of problem solving, all undertake the same basic phases. For the purposes of this discussion the four-step model of problem solving outlined by Bergan (1977; Bergan & Kratochwill, 1990) will be used. Those steps are problem identification, problem analysis, plan development and implementation, and problem evaluation. Also, to at least some extent, all approaches to consultative problem solving emphasize the importance of developing a collaborative relationship. Because this chapter's authors believe it is vitally important to collaborate meaningfully with teachers, parents, and students in problem solving, this chapter highlights the importance of collaboration at each step in problem solving.

This problem-solving process can be successfully applied to a whole spectrum of problem situations occurring in schools. Because of space limitations, this chapter will be devoted to an overview of the model as applied to problems of individual student performance, which might be addressed at either the individual or group consultation levels of problem-solving service delivery. It is important to note, however, that the same model and decision-making processes can be used to address problem situations applicable to different organizational levels, such as classroom- or building-level issues. For example, occasionally a school may repeatedly experience the same type of referral problems. When this occurs, it may be decided that some sort of programmatic interventions need to be implemented. Such a decision also is well within the purpose of a problem-solving approach to intervention design. Although the context to be examined differs to some degree, the decisions that have to be made by problem solvers are extremely similar.

The following discussion is intended to provide a clear understanding of the sequence and type of decisions that problem solvers must make when presented with a student who is not meeting expectations. The decisions that need to be made are the same for students with and without disabilities as well as for academic or behavioral problems. For each step in the problem-solving process, the *questions* that must be answered, the *tasks* that need to be completed to answer these questions, some *methods* for accomplishing the tasks, and the *outcomes* of the step are highlighted. Links between assessment and intervention will occur as the implications of decisions made at each step of problem solving must be used to inform the subsequent steps. That is, the design, implementation, and evaluation of interventions aimed at resolving problem situations are presented.

Problem Identification: What is the Problem?

The objective of the first phase of problem solving is specific problem identification. Premised on the assumption that the problem is situation-centered within an educational environment, the intent of this initial phase is to clearly define the discrepancy between expected and actual performance in a particular setting. Specifically, the problem is defined based on the mismatch between what people expect of the student to be successful in the environment and the student's current level of performance.

Questions to be asked at this phase include: What is the problem? Specifically, what is the student doing (or not doing) that has caused someone to perceive a problem? In defining and clarifying the problem to systematically include environmental factors in the problem identification, the question is broadened to: What is the problem situation? For example, a student is out of his assigned seat during large-group instruction periods, or a student is hitting other children when she does not receive an item requested. Rather than identifying problems such as a student is "unmotivated" or "learning disabled," it is necessary to ask what the student is doing (or not doing) that the teacher has come to label in these general terms. In this case, it may be that the student does not turn in her assigned paper at the end of class or that he looks down and does not respond when called on during a class discussion.

To answer these questions, a number of *tasks* need to be accomplished during this phase of problem solving. Conceptualized as a funnel, the problem identification process should begin from a broad base to identify all concerns regarding a problem situation. First, problems may be described in general, global terms. As the funnel narrows, however, the problem(s) being identified must also be defined and clarified in more specific terms. For example, because problem situations often are complex in nature, it may be necessary to break the problem into component parts and, subsequently, to prioritize them either in terms of sequence (e.g., short-term and long-term) or importance (e.g., most critical based on potential for harm). Additionally, research (Bergan & Tombari, 1976) has shown that when problem situations are defined in observable, operational terms, the probability of successful problem resolution is significantly higher. Conversely, when a consultant introduced a medical-model label or internal child attribution or explanation into the interaction (e.g., child has ADHD), the teacher took less responsibility for problem resolution and problem solving efforts were less successful (Tombari & Bergan, 1978).

Therefore, beginning with top priority problems, specific target behaviors should be defined for each. Each problem should be stated in concrete, behavioral terms that can be both observed and measured. In addition to being representative of the problem area, specific target behaviors should also be socially valid and meaningful. That is, if these behaviors were changed, the primary caregiver's concerns would be alleviated. As a result, the input of the primary caregiver is critical to this and each of the remaining stages of problem solving.

Lastly, it is important that positive replacement behaviors be specified for each identified problem. Also stated in concrete, easy-to-measure, behavioral terms, goals should be generated as a criterion for assessing intervention effect. What is the expected outcome? What level of performance will the student need to reach (or not reach) to meet expectations? The target behaviors that will be increased and/or decreased also should be clearly defined and agreed upon by all participants.

Incorporated into all phases of collaborative problem solving, assessment may not be extensive during this phase but it does begin during problem identification. Because the concerns identified as part of this initial phase of problem solving represent what is perceived to be the problem and what must be changed if intervention is to be regarded as successful, assessment may be used to gather information needed in defining and clarifying a child's current performance or skills as well as environmental variables. Particular *methods* of assessment that may be used include interviews with teacher, parents, and/or the child; review of school grades and other records; review of work samples; direct observations; and behavioral rating. Finally, the *outcome* of this step is specific delineation of the problem situation in terms of target behavior(s) and replacement behavior(s).

Throughout problem identification, collaboration occurs by the consultant eliciting from the teacher, parent, and/or student their specific concerns and goals, and clarifying understanding of these. The consultant's role in this collaboration is to facilitate the problem-solving process and completion of the steps. The participant's role is to provide the best information he or she can about the concern. In terms of decision making, the person presenting the concern, not the consultant, makes the decision about which problems are priorities and which targets to include. Thus, the primary ownership for defining the situation of concern rests with the persons experiencing the problem situation (e.g., the teacher, student, parents).

Problem Analysis: Why is the Problem Situation Occurring?

Making decisions regarding why the problem situation is occurring corresponds to the second phase of problem solving, problem analysis. In answering questions about what "causes" a student to fail to meet expectations, the objectives are to understand the behavior in context and to form a hypothesis about why the problem situation is occurring so that an appropriate intervention can be developed. If the interventions developed later are to match the reasons that the problem exists, the decisions made here obviously are important. The selection, use, and interpretation of assessment tools are critical in determining the validity and reliability of information derived from the problem-analysis phase of problem solving. The focus is on *direct* assessment of variables that help guide intervention choices. Information is collected to answer specific questions in a direct and parsimonious manner. Assessment that does not have direct implications for intervention design is not completed.

The processes of problem solving in general, and problem analysis in particular, are not necessarily linked to any theoretical orientation. Problem solving does provide a systematic process for addressing problem situations; however, the application of this framework can be useful in guiding service delivery premised on various theoretical models. Neither the process, the questions to be answered, nor the tasks that need to be accomplished at each step in the problem-solving process will change dependent upon one's theoretical orientation. However, the hypotheses and the answers that result will be different dependent upon the theoretical orientation of problem solvers due to the way each conceptualizes the issues, interprets the information gathered, and so forth. Given that this chapter's authors endorse an ecological orientation, for example, our conceptualization of a problem situation and the factors causing it would not be limited to sole focus on child variables. Rather, our analysis of the causes of the problem situation would include consideration of the skills and behavior of the child, his/her teacher, and the environmental context in which the problem situation is occurring.

The *questions* that need to be answered during the problem analysis phase of problem solving include: Why is this problem situation occurring? What factors are contributing to the mismatch that exists between actual and desired levels of performance for each target behavior? What resources are available to help resolve this problem situation?

To answer these questions, all of the factors possibly related to the problem situation need to be analyzed — both those factors serving as obstacles inhibiting desired performance and those which might serve as supportive factors or resources in resolving the problem situation. In particular, attention should be given to variables directly relevant to the problem situation and, therefore, possible areas for intervention planning. Readers are referred to the Batsche and Knoff chapter in this book for a discussion of domains or conditions that need to be considered when attempting to understand why the problem situation is occurring. Complete descriptions of behavioral approaches to problem analysis can be found in texts devoted to elaborating these procedures (for example, Martin & Pear, 1992; Shapiro, 1989; Shapiro & Lentz, 1986).

There are several general *considerations and tasks* for assessment at this stage of problem solving. First, the situational context in which problems are occurring should be carefully assessed. For example, a functional analysis of the problem situation could be conducted to examine antecedents, behaviors, and consequences. Second, exceptions to the problem situation might be examined. That is, what are the environmental conditions when the problem behavior is not occurring or when performance is better? Particular note should be made of conditions that can be altered as they may be useful targets for change in intervention planning. Finally, resources or factors supportive of resolving the problem situation should be identified.

In general, the goal of problem analysis is to determine a functional relationship between independent and dependent variables within this environmental context (Greenwood, Carta, & Atwater, 1991). There are various types and approaches to assessment that might be used during the problem analysis phase. Together participants must decide how best to answer the questions being asked about the cause of this problem situation. As a rule, however, comprehensive assessment within a problem-solving framework includes multiple procedures and sources of information. That is, for the purposes of problem analysis, assessment should be conducted across multiple environments, domains and times, and use multiple methods.

As additional information is needed to clearly understand the cause of the problem situation, specific questions should be generated collaboratively to guide further assessment. It is important to remember that assessment is the process of asking questions and generating information to answer questions. Therefore, assessment questions should focus on solving the current problem situation rather than just "admiring" it. That is, assessment questions and methods must be intervention oriented. In this framework, if assessment will not have direct intervention links, it is not completed. Examples of *methods* most directly useful for intervention purposes include systematic and directed observation, structured interviewing with those most familiar with the problem situation, functional analysis, curriculum-based assessment and measurement, behavioral rating scales, performance-based assessment, review of records, and permanent products such as classwork.

Collaboration as a method underlies all that is accomplished at this step. All data collected and all questions generated must be developed collaboratively and must serve the purpose of helping to develop interventions to improve the situation. The consultant does not serve in an expert role of deciding what information needs to be collected and how it will be collected. Nor does the consultant own the assessment information and its interpretation once it is collected. Rather, the teacher or intervenor should ideally be the "expert" in terms of a thorough understanding of the problem and its context. If assessment information is seen as the domain of an outside expert such as the school psychologist, the teacher or parent cannot be an active partner in problem analysis. From this collaborative perspective on problem analysis, all decisions about what data to collect, how to collect it, and how to use it are driven by collaboration. Thus, classroom observation data are collected to answer a specific intervention-related question, not to "verify" a teacher observation.

For example, observation could occur when there is a mutually agreed upon decision that more specific data are needed on a variable such as time on task, number of interruptions, or triggers for disruptive behavior. In this collaborative model, all forms of data collection are seen as answering questions generated earlier by the collaborators. It should be obvious that much of the data that school psychologists routinely collect for the purpose of determining special education eligibility as mandated by state rules and regulations do not serve the collaborative model. However, in this situation, the school psychologist can make clear distinctions between data collected for intervention design and data collected to meet mandates. Also, the emphasis can be on data that help with intervention design.

From information generated during problem analysis, the *outcomes* of this step will be (a) an identification of the discrepancy between actual and desired level for each target behavior, (b) the setting of a specific outcome goal(s) for the intervention that will follow, and (c) a sufficient understanding of the problem situation and contextual variables to decide on an intervention plan to improve the situation. Based on this result of problem analysis, it sometimes is necessary to refine the target behavior.

Plan Implementation: What Can Be Done to Resolve the Current Problem Situation?

Once the problem situation is clearly identified and understood, the focus of the problem-solving process turns to the task of designing an intervention to resolve the problem. Related to the task of intervention planning, this next step in the problem-solving process can be divided into several phases, each with their own questions to be answered and tasks to be accomplished. Specifically, these phases include exploring alternative intervention strategies, selecting intervention(s), clarifying intervention plans, and implementing the chosen intervention(s).

Explore alternative intervention strategies. In posing the *questions*, "what needs to be changed and how is that going to be done?" the first phase of intervention planning aims to explore alternative intervention strategies that could be tried to improve the problem situation. In so doing, the intent is to generate and explore a wide range of possible strategies for consideration by the person(s) responsible for implementing the intervention.

To be effective, interventions must be logically related to the identified problem and to the reasons that the problem situation exists. Therefore, the exploration and selection of intervention strategies is based on specific information derived from problem analysis. By discussing the factors that contribute to the mismatch between current and expected performance, problem-solving participants should begin to identify strategies for intervention. Consideration is given both to changing relevant context variables within the environment and to changing relevant skills or behavior of the student, teacher, and others.

Participants are encouraged to think creatively in generating possible intervention strategies and beyond the traditional use of resources such as placing a child in an existing program or classroom. At the same time, it is important to explore interventions within the control of those in the situation. That is, intervention strategies should consist of actions that participants can either prepare for or begin implementing tomorrow. When identifying strategies, all participants assume responsibility for contributing ideas and considering options so that the process remains collaborative. Instead of presenting primary caregivers with the "solution," participants should offer ideas as possibilities for consideration.

In collaborative problem solving, the school psychologist does not recommend action plans to the teacher as has been done in traditional psychoeducational reports. Rather, like each of the other participants, the school psychologist has the responsibility to contribute his or her knowledge and expertise so that participants can consider and evaluate alternatives. Ultimately, it will be the primary caregiver(s) who assumes responsibility for implementation of the intervention plan. As such, she or he will also be the person best able to determine the appropriateness or acceptability of proposed strategies. In fact, often some of the best ideas are generated by the persons most familiar with the problem situation. Certainly they are in the best position to evaluate their ability and willingness to implement a proposed intervention plan.

Select intervention plan(s). From among the many alternatives considered, specific intervention strategies must be chosen and an intervention plan outlined. Answers generated to the questions posed in previous steps are used to respond to the **question** that must be answered at this phase in the problem-solving process — "what intervention(s) should be tried to improve the problem situation?"

With regard to the *task* of selecting an intervention plan, there are several important issues to be considered. First, consistent with the notion of collaboration, responsibility for selecting an intervention strategy must rest with the person(s) who eventually will implement it. Given the collaborative nature of the problem-solving process, all participants share responsibility for brainstorming and evaluating alternative interventions. However, because the person(s) most directly involved in the problem situation assume primary responsibility for plan implementation, they are given final choice in the selection of intervention plans. Clearly, if an intervention is unacceptable to the person who is supposed to implement it, it is unlikely that it will ever be implemented as intended.

Another important consideration relative to the task of selecting an intervention plan is the likelihood of success in changing the problem situation. Based on the findings from problem analysis, a determination is made regarding what should be changed and what can be changed. With a focus on "alterable" variables, the selection of interventions should consider what are the most natural, least intrusive, and most effective strategies for accomplishing change. That is, to what extent do these strategies fit with current classroom routine and teaching practices? What, if any, positive effects are likely to result in other students? Finally, in judging the potential efficacy of an intervention plan, consideration is given to issues of feasibility, including the availability of resources.

Clarify the intervention plan. Once an intervention plan has been selected, it is important to clarify all aspects of the procedures. In particular, all participants should agree on a written action plan that specifies (a) every component of the intervention plan, (b) person(s) responsible for each component, (c) setting(s) where the intervention will be conducted, and (d) beginning and review dates. Simply stated, the action plan needs to answer the *question* of "How will the intervention occur to improve the problem situation?" by considering who will do what, when, where, and how.

Also, clearly outlined as a portion of the intervention plan are procedures and a schedule for monitoring progress toward goals. Specifically, participants will need to answer the important *questions* of "How will we know that the intervention is working?" and "How will we show others that the intervention is working?"

In addition to establishing a brief repeated measure that may be used to assess target behaviors, a progress monitoring plan must include a timeline for intervention, goals or criteria for performance, and a decision-making system that allows for interventions to be changed when they do not produce the desired outcome.

Implement intervention plan. The primary responsibility for implementation of the chosen intervention plan is assumed by the individual(s) (e.g., teacher, parent) who spends the most time in setting(s) when interventions are being implemented rather than by support personnel such as school psychologists. However, it is the responsibility of *all* participants during the implementation phase to provide ongoing support for the intervention plan and for their collaborators. In our experience with implementing collaborative problem solving in schools, collaboration is most evident when all of the individuals who helped to develop the intervention plan also have a role in its implementation. For example, the teacher could direct implementation of the instructional strategy, the school psychologist could help set up the data-monitoring plan, and chart and direct data collection, the student could chart and self-monitor goal attainment, and the parents could reinforce goal attainment through rewards at home. The *question* to be answered at this phase in the problem-solving process is "How can we best support the intervention and the intervenor(s) during implementation?"

In response to this question, the *tasks* that need to be accomplished include providing ongoing support and systematic follow-up with intervention implementation. For example, it is important to provide those participants directly involved with implementation of the planned intervention with encouragement and positive feedback for their efforts. Additionally, support may be needed in gathering resources and collecting data. To ensure that interventions are being implemented as outlined, certain participants may need to provide support by trouble-shooting with the intervenor(s), providing technical assistance with intervention procedures, and/or monitoring treatment integrity.

Problem Evaluation: Is the Intervention Plan Working or Does It Need to be Changed?

In the problem-solving approach, an intervention is treated as a testable hypothesis, not a known solution. As such, assessment is an ongoing process and progress toward attainment of desired outcomes is monitored continually. After giving interventions sufficient time to be implemented, participants evaluate data regarding target behaviors and make decisions about whether the degree of progress being made toward each goal is adequate.

The principal *question* to be answered during the problem evaluation step is "How well is the intervention working?" Depending on the answer received, participants may need to ask follow-up questions. Specifically, if the goals of the intervention program are met, the focus of questions that follow will address issues in maintenance and/or generalization. For example, "Is the problem resolved or is there a need to continue an intervention?" "How will the intervention be faded in order to maintain the improvement?" and "How can the intervention strategies be applied to other settings in which the problem occurs?" If intervention outcomes are not satisfactory, it will be necessary to answer questions such as, "Is it certain that the intervention plan was implemented consistently as outlined?" and "What information was missed during problem analysis?"

To decide whether the intervention plan is working, problem solvers need to undertake several *tasks*. Specifically, the data collected through ongoing assessment needs to be examined to determine if the progress toward meeting goals is adequate. Subsequently, participants need to examine the implementation of the intervention plan, discuss problems, and decide if any changes are needed.

Based on the determinations made regarding the adequacy of the current intervention strategies meeting goals, problem solvers should undertake one of several alternative *tasks*. Specifically, if the intervention has been successful, it will be necessary to decide whether to (a) continue with the current intervention plan; (b) outline strategies to phase out the current intervention procedures, with consideration for generalizing to alternative settings or target behavior, or for maintenance within the natural setting; or (c) progress toward the next goal.

However, if it is decided that the interventions have not been effective in producing the desired changes in the problem situation, it may be necessary to recycle to an earlier step in the problem-solving process. If so, the tasks facing participants include reconsidering the questions addressed in an earlier step, such as target behaviors, situational variables contributing to the problem situation, or the nature of an intervention strategy. Alternatively, if the outcomes of an intervention plan are not effective, it may be necessary for participants to pursue more in-depth or extended problem solving. That is, it may be necessary to access additional resources and supports by taking the problem to a higher level on the continuum of service delivery options (e.g., request consultative assistance at group problem-solving level rather than at individual level).

Consistent with a problem-solving approach, progress toward desired outcomes is monitored through ongoing assessment. Data are used to determine whether interventions are working, whether goals are being met, or if the intervention plan needs to be changed. Based on the information derived from assessment data, all participants work cooperatively to evaluate outcomes, and decide both whether and how intervention plans may need to be modified in order to enhance progress. Having agreed, during the initial stages, about what the problem situation was and which behavior changes would indicate improvement, participants should find this question easy to answer.

Flexibility in Problem-Solving Sequence Implementation

Actual problem solving rarely proceeds in a sequence as orderly as described. Rather it is often necessary to move back and forth between steps, or, sometimes, to recycle to an earlier step in the process as new information is gathered, communication among participants improves, and the like. Nevertheless, the model described provides a framework that may be used as a flexible guideline for the ordering of steps, not as a rigid sequence of events.

SUMMARY

Given our common interest in supporting and addressing the needs of students, it becomes incumbent upon us (e.g., school professionals, parents, community members) to work together to solve problems. Recognizing that each participant will make different contributions to the process, it is important to realize that each also enhances the probability of reaching an effective solution to this particular problem situation. For school psychologists, perhaps the most important contributions that can be made are through facilitating the process used to address problem situations. Rathr than directing our energy at producing "the" right answer, school psychologists can work to establish ongoing relationship with and among other concerned individuals. And secondly, we have the expertise to guide the use of a framework that all participants can use in systematically addressing the problem situation. A collaborative problem solving approach to intervention design provides a model school psychologists might use in doing so.

ANNOTATED BIBLIOGRAPHY

Conoley, J. C., & Conoley, C. W. (1992). *School consultation: Practice and training* (2nd ed.). New York: Macmillan.
Written with the needs of practitioners in mind, this book provides a practical, straightforward guide to consultation in the schools that can be useful to both experienced and beginning problem solvers. Although each of the major approaches to consultation are presented, an ecological model provides the basis for discussions of implementation and ethical issues, necessary skills, pragmatic ways of evaluating effectiveness, and common obstacles to practice. Annotated case transcripts, suggested readings and references are used to expand upon the information discussed in the chapters.

Friend, M., & Cook, L. (1992). *Interactions: Collaboration skills for school professionals.* New York: Longman.
With an emphasis on interpersonal interactions among individuals and groups, this practical volume provides a detailed overview of collaboration skills. Both collaboration contexts, and interpersonal skills essential to effective consultative problem solving — listening, communicating, questioning, framing statements, and providing feedback — are covered in detail with practical application examples and practice activities for each. This book is an excellent introduction for educators without specific training in interpersonal aspects of collaboration and a useful refresher for experienced school psychologists regarding communication skills as applied to collaborative problem solving.

Kratochwill, T. R., & Bergan, J. R. (1990). *Behavioral consultation in applied settings: An individual guide.* New York: Plenum Press.
Intended to be a skill-training guidebook for practitioners interested in learning a behavioral consultation approach to the design and delivery of behavioral interventions in applied settings, this book can be used independently or as a supplement to a text by the same authors (Bergan & Kratochwill, 1990) and/or supervised training in collaborative problem solving. Objectives and procedures are detailed for each of the four stages in the problem solving process, along with some sample interview formats. The content presented in each chapter is expanded with examples and discussion of transcripts from consultation interviews, discussion questions, and self-quizzes.

Shapiro, E. S. (1989). *Academic skill problems: Direct assessment and intervention.* New York: Guilford.
Effective collaborative problem solving for the purpose of intervention design requires that problem solvers have a strong foundation in direct, intervention-oriented assessment, knowledge of effective classroom interventions, and skills in the use of methods to systematically plan and monitor assessment and interventions. This book is an excellent source of extensive, detailed information on each of these topics, with a particular emphasis on academic skills assessment and intervention. Practical guidelines, steps to follow in the process, and coverage of the knowledge base in several areas important to understand-

ing classrooms (e.g., ecological assessment, interviewing frameworks for focusing on academic variables) are included. Helpful information is included on several specific assessment and data monitoring strategies, including curriculum-based assessment.

ACKNOWLEDGMENTS

The conceptualizations and examples found in this chapter have been shaped by the influence of many colleagues, and we want to gratefully acknowledge their contributions to our thinking. These individuals include our colleagues at the University of Cincinnati, David Barnett and F. Edward Lentz, as well as our many skilled students and graduates, whom we thank for their contributions to how we view problem solving. We also are indebted to the many educators and parents we have worked with in schools who continue to teach us about practical implementation of collaborative problem solving.

FOOTNOTE

We attribute the phrase "admiring the problem" to James Ysseldyke from whom we first heard this term several years ago. We believe it accurately captures the essence of many of the activities of multifactored evaluation teams that focus on finding and documenting student deficits, which Seymour Sarason has referred to previously as a "search for pathology."

Best Practices in Assessing Environmental Factors That Impact Student Performance

Maura L. Roberts
Illinois State University

OVERVIEW

Many procedures and measures have been used to assess academic performance throughout the years. The field of school psychology has been represented by different theoretical approaches which affect the selection of assessment instruments and interpretation of target behaviors. Regardless of these differences, the overall goal of assessment should be to design interventions. To achieve this goal, assessment procedures must be directly linked to an intervention for the target behavior. This link, however, can only be established by assessing the relationship between academic problems and critical variables in the classroom. In fact, to design and implement effective interventions, all factors that influence learning outcomes need to be assessed. Therefore, this chapter discusses the best practices for an alternative service delivery model that links assessment to intervention and highlights some of the most important environmental variables that impact student performance. Specifically, best practices for assessing the classroom environment will include the use of teacher interviews, direct observations, permanent products, curriculum-based measurement probes, and the evaluation of interventions/treatment procedures. Important environmental variables related to student, classroom, and instructional variables will also be discussed.

BASIC CONSIDERATIONS

Historically, educators have characterized traditional psychoeducational assessment and decision-making practices as a "search for pathology." These procedures tend to use instruments that primarily focus on within-student variables and processing deficits related to academic difficulties termed poor cognitive abilities (Lentz & Shapiro, 1986). Often school failure is attributed to these within-student characteristics. In other words, the emphasis of a diagnosis implies that something is "wrong" with the child rather than environmental variables. Therefore, psychoeducational evaluations are often administered for the purpose of identifying within-student deficits or disabilities that are presumed to "cause" educational difficulties (Algozzine, Ysseldyke, & Hill, 1982; Ysseldyke & Christenson, 1987; Ysseldyke, Regan, Thurlow, & Schwartz, 1981). Unfortunately, this type of assessment ignores environmental and instructional factors within the classroom that influence a student's performance. To remediate problems, school psychologists need to use assessment procedures that analyze the relationship of an academic problem to critical variables within the classroom environment.

Because of the limitations of traditional assessment, researchers and educators have designed new approaches to evaluate students in an academic environment — standardized observational codes and curriculum-based assessment. This alternative service delivery model has emphasized a direct link between assessment and intervention in primarily three ways:

1. Assessment information must be directly linked to interventions specifically designed for the target student's needs.

2. Assessment must examine the relationship between academic skills and the classroom environment.

3. The assessment process should be continuous to determine the success of interventions and make treatment modifications when necessary (Lentz & Shapiro, 1986).

Psychologists also need to assess and have a clear understanding of the complex interactions of the academic environment. Later in the chapter some of the critical variables in a structured environment that can impact student performance will be discussed. These variables fall into three groups: (a) student characteristics, (b) classroom environments, and (c) instructional practices.

BEST PRACTICES

In order to understand students in a structured environment, the psychologist should include in the assessment process (a) teacher interviews, (b) direct classroom observations, (c) analysis of permanent products, (d) the administration of curriculum-based measurement probes, and (e) treatment evaluation. Each of these assessment methods is designed to evaluate particular variables related to academic performance. Furthermore, these assessment techniques determine academic performance as well as their interaction with critical factors within the classroom. These procedures also provide information that can be directly linked to interventions and remediation of target behaviors.

Teacher Interviews

The primary objective of the teacher interview is to obtain a clear, operational definition of the target behavior and the classroom environment. Bergan's (1977) behavioral consultation model provides an excellent structure for psychologists conducting teacher interviews. This model explicitly outlines four types of interviews: problem identification, problem analysis, plan implementation, and plan evaluation. Each interview format allows the psychologist to analyze the structured environment and identify specific variables that may interfere with performance. These interviews not only help identify the problem, but each interview works toward planning and implementing interventions. In fact, Lentz and Shapiro (1986) recommend the use of the problem identification and analysis interviews for assessment and remedial planning, and the plan implementation and evaluation interviews for assessing treatment effectiveness.

In addition to Bergan's interview formats, Shapiro (1989) provides an excellent structure for conducting the teacher interview. The objectives of Shapiro's teacher-interview format are to help psychologists identify the problem, analyze the critical variables related to the problem (e.g., antecedent and consequences), and provide some indication of student skill level in reading, math, spelling, and written expression. Again, this format is designed to help psychologists obtain a clear definition of the presenting academic difficulties and related environmental events. Other variables specifically related to the target behavior that should be included in the teacher interview include instructional procedures, current level and placement in the curriculum, child performance, contingencies for performance, and classroom participation. Once a problem has been analyzed, additional interviews can permit teachers and psychologists to plan and evaluate interventions.

Direct Observations.

Following the problem identification interview, repeated observations need to be conducted to collect objective data on the student's interaction in the academic environment. Ideally, direct observations of the referred student should be conducted during the part of the school day in which the referral concern or target behavior occurs. The primary goal of direct observations is to obtain data that verify the teacher reports and establish an accurate and objective picture of the student's typical classroom behavior. Direct observations also enable psychologists to analyze the relationship between antecedents and consequences that may be maintaining the target behavior in the classroom.

When conducting classroom observations, the psychologist would do well to use highly standardized observational codes with protocols and standard definitions and procedures. Standardization helps ensure that the data collected are reliable, valid, and clearly communicated. The State-Event Classroom Observation System (Saudargas & Creed, 1982), Code of Instructional Student and Academic Responses (Stanley & Greenwood, 1981), and The Instructional Environment Scale (Ysseldyke & Christenson, 1987b) are all examples of standardized observation codes that can be used for direct classroom observations. All of these codes systematically describe the extent to which a student's academic or behavior problems are a function of the factors in the structured environment and help identify starting points in designing appropriate interventions. Observational data, such as out-of-seat behavior and on-task behavior, can also be collected subsequent to the assessment process to evaluate interventions' effectiveness.

Permanent Products

Whenever a direct observation is made, it is imperative that psychologists examine work produced during that time and compare these products to less direct measures of engagement (e.g., time on-task and orientation to material). Permanent products provide excellent samples of written responses of skills that students are required to perform or master. Other examples of permanent products include daily independent worksheets, homework, tests, and progress evaluations. Permanent products can be utilized during the initial teacher interview to help identify target skill areas. In fact, it is recommended that teachers maintain copies of the referred child's work products throughout the assessment and intervention process to measure changes in performance. Psychologists can also assess permanent products to determine the quality of response opportunities during independent seatwork. Specifically, permanent products can be analyzed to determine the types of errors typically made by the students (e.g., forgetting the beginning or ending of spelling words or difficulties regrouping math problems). Information obtained from an error analysis can help specify the interventions to remediate the problem. Furthermore, psychologists can continue to analyze the number of error responses to evaluate the success of interventions that are implemented (Lentz & Shapiro, 1986; Shapiro, 1989).

Curriculum-Based Measurement

Psychologists often administer various kinds of tests to determine a student's learning or academic achievement in the schools. More recently, educators have cited some limitations of traditional standardized norm-referenced measures (Deno, 1985; Tucker, 1985). A primary limitation is their inadequacy in measuring the outcomes of educational decisions, because they do not reflect small changes in student academic progress (Marston, Fuchs, & Deno, 1986). Secondly, these tests provide little information to help facilitate appropriate and effective interventions for academic difficulties within the classroom (Deno, 1985). Based on the limitations of traditional assessment, researchers and educators have begun to design new approaches to educational evaluation that provide objective long-term measurement of learning. Each of these measures attempts to link the assessment process to the curriculum and instruction, to allow on-going monitoring of progress in the curriculum, and to help identify a student's instructional needs (Shapiro & Derr, 1990).

Among the recently developed approaches to educational evaluation is curriculum-based assessment (CBA). CBA can be defined as "any set of measurement procedures that use direct observation and recording of a student's performance in the local curriculum as a basis for gathering information to make instructional decisions" (Deno, 1985, p. 41). These assessment procedures are derived directly from the curriculum material in which the child is being instructed to determine how much of that material the child has mastered. Furthermore, CBA procedures require only a series of brief, timed-skill probes which can be conducted in the areas of reading, spelling, mathematics, and written expression. In addition, CBA procedures can be used to create local normative samples and serve as a basis for making education decisions regarding student academic performance and growth at the local (school or classroom) level.

Since the conceptualization of CBA, different models have been developed, each with a different focus and/or set of procedures, and each designed to address different aspects of a student's academic performance (Shapiro, 1990). However, all CBA models are designed to: (a) provide improved links between the assessment and intervention processes, (b) employ direct measurement procedures, (c) use frequent and repeated measurement, and (d) rely on test administration of short duration. For example, Deno's (1985) model of curriculum-based measurement (CBM) is designed to decrease the gap between measurement and instruction by integrating a student's achievement data with a teacher's daily instructional decisions. The four major assumptions of CBM are:

1. Modifications in instructional programs for individual students should be empirically tested before their effectiveness can be evaluated.

2. Time-series research designs are appropriate for monitoring and evaluating instructional program changes.

3. Applying time-series designs requires the specification of data representing academic progress in school years.

4. Time-series designs can discriminate between students who are in special and regular education programs (Deno, 1985).

In comparison to CBM measures, standardized achievement tests yield only norm-referenced scores, reflecting a student's relative standing within some reference group. Such measures do not yield any information regarding student competence within the curriculum and also fail to reflect a student's performance within the curriculum relative to his or her peer group. Similarly, achievement tests cannot generate data points frequently enough to establish the actual rate of student growth. Furthermore, CBM is sensitive to specific academic progress, unlike standardized achievement measures, which fail to show any student growth for up to 16 weeks (Friedman, 1990; Marston, Fuchs, & Deno, 1986). Within a short duration of time, CBM data reflect changes in a student's performance (as displayed in slope of improvement) which allow teachers and psychologists to frequently monitor academic performance.

In relation to special education placement decisions (Deno, Marston, & Tindal, 1986), CBM data can be used for screening and identification of students in need of special services by evaluating ratios between actual and expected performance as determined through collection of peer performance. Current performance levels can also be the basis for developing appropriate goals for the Individualized Education Plan and progress can be evaluated to facilitate timely and appropriate modifications in the program (Deno et al., 1986). Clearly, data already exist on the effectiveness of CBM, thus providing a strong support for its continued use and importance in educational assessment.

Direct Measurement of Intervention Effectiveness

Once the assessment process is completed, the repeated use of observations and CBM data can be used to determine the effectiveness of interventions. In particular, CBM data can be used to construct progress/performance graphs. These procedures allow psychologists to regularly obtain brief samples of student performance. These data can be graphically displayed in a series of repeated measures to describe a student's current level of performance. For example, the dependent measures, such as words read correctly, of CBM data can be graphed and the slope of these data can estimate the student's rate of curricular progress (Deno, 1985). Thus, CBM yields a slope of improvement unobtainable when using standardized achievement tests. These graphs also help clearly and effectively communicate a student's rate of achievement to teachers, parents, and students. Therefore, CBM allows teachers and psychologists to frequently monitor and evaluate the instructional effectiveness of interventions in order to efficiently solve a student's achievement problems.

ENVIRONMENTAL VARIABLES IMPORTANT TO ASSESSMENT

Student Characteristics

In order to understand and remediate academic problems, psychologists must examine student characteristics, as well as the classroom and instructional variables that influence learning. The most successful technologies for remediating academic problems involve direct instruction for skill deficits and/or manipulation of environmental variables impinging on student performance (Lentz & Shapiro, 1986). Academic skills, time needed to learn, and motivational factors are three examples of student characteristics that are often cited in the professional literature.

When assessing academic skills, psychologists need to differentiate between a skill and a performance deficit; this information is crucial for designing interventions. A skill deficit would indicate that a child's academic repertoire does not include the necessary skill or skills required to complete an academic task. For these children, variables such as the pace of instruction, opportunities for practice, and missing entry-level skills may be factors contributing to the skill deficit. On the other hand, a performance deficit would suggest a child has the academic skill or skills in his or her repertoire, but is not exhibiting the required behavior in the environment. For these children, contingencies for accuracy, completion of schoolwork, motivation, off-task behavior, and understanding the expectations for the assignment may be interfering with performance. Once the variables impinging on a child's skill or performance acquisition are identified, interventions specifically designed to meet a student's needs can be constructed.

Another student characteristic related to academic performance is the time each student requires to learn new information. Although research suggests that student rates of acquisition are considerably different, there seems to be a direct relationship between a student's cognitive ability, as measured by IQ, and the number of repetitions to acquire new material. Research suggests that students with high IQs (120–129) need fewer repetitions (20) compared to students with lower IQs (60–69; repetitions = 55). There is also evidence to suggest that students with IQs between 90–109 should be provided with 35 repetitions to achieve rapid and accurate recognition of new academic material. Clearly, automaticity and accuracy of responding can be greatly enhanced by increasing the number of repetitions of new information (Gates, 1930; Hargis, Terhaar-Yonkers, Williams, & Reed, 1988).

Lastly, the effect of motivation on student learning and performance is a crucial variable that needs to be assessed in the classroom. Although student motivation is often conceptualized as an internal process, it can be externally managed to dramatically affect change by using incentives for accuracy and completion of task-related assignments. Reinforcement programs and self-management techniques (e.g., contingency contracting, self-monitoring) can effectively motivate students in the classroom. Ysseldyke and Christenson (1987a) suggest the following strategies to increase a student's motivation to learn: vary assignments, set individual goals for learning and performance, assign tasks at a child's appropriate instructional level, clearly define contingencies for completing or not completing work, and regularly schedule conferences with students regarding performance. Given the importance of these motivation factors, psychologists need to determine the extent to which these practices are implemented and/or influence a student's target behavior. Suggested methods for assessing these student variables can be found in Table 1.

Classroom Environment

Many variables within the classroom environment can affect a student's classroom behavior and academic performance. For example, large group-size classrooms with minimal teacher supervision have been found to result in increases in classroom misbehavior (Jason & Nelson, 1980). Other research indicates that different classroom environments result in different student motivational goals (Covington & Omelich, 1984). When assessing the classroom environment, psychologists should pay particular attention to assessing variables related to academic engaged time (allocated time, on-task, opportunities to respond), classroom management (transitions, rules, physical arrangement) and the direction and frequency of teacher attention. Often these factors can interact with learning and can affect performance in the classroom.

Academic engaged time represents one of the most potent classroom variables affecting student achievement. Academic engagement can be defined as making frequent, accurate responses to stimuli or to relevant tasks to be learned, maintained, generalized, or adapted. The three variables related to academic engagement are: (a) allocated instructional

TABLE 1
Suggested Assessment Methods for Student Characteristics Related to Academic Performance

Ability to understand instruction	X	X	X	
Affective characteristics	X	X		

time, (b) on-task behavior, and (c) opportunities to respond (Lentz & Shapiro, 1986). Regardless of a student's characteristics or cognitive abilities, academic engagement is required to make adequate progress in the curriculum (Rosenshine, 1981).

Allocated instructional time is a general concept of academic engagement which refers to the amount of time actually available for students to work in the classroom (e.g., 30 minutes of math instruction). It consists of the time scheduled for instruction and the time available for students to work. In general, the amount of time a student can be academically engaged in the classroom is determined by allocated time. Therefore, the relationship between achievement and engagement is directly related to the amount of time allocated to work, and, more specifically, to the student's orientation to the task and appropriateness of academic responding.

In order to determine a student's use of allocated time, school psychologists should assess a child's on-task or "attention to task" behavior during instruction and work time, especially since such behaviors seem to be an important predictor of student achievement (Good & Brophy, 1984). There are many considerations and clues in this variable. For example, there may be differences between the percentage of time on-task during independent seatwork and during group instruction. Or a child who is off-task a high percentage of the time may have difficulty completing assignments or may not take advantage of opportunities to practice and acquire a new skill. Yet, a child may be on-task a high percentage of the time and still have lower rates of academic responding or task completion (Ferritor, Buckholdt, Hamblin, & Smith, 1972). This may indicate a deficit in the child's academic skill repertoire. For example, a child who has just acquired a new skill may not be fluent in performing the skill and, therefore, need a longer period of time to complete an assignment.

The most specific and important variable related to academic engagement, however, is the number of opportunities to respond academically (Greenwood, Delquadri, & Hall, 1984). Opportunities to respond is defined as the number and type of student academic responses per time unit. Some examples include independent seatwork, cooperative learning, and accurate responses in small- and large-group instruction. Implementing strategies to increase opportunities to respond can greatly improve academic performance in the classroom (Rosenshine & Berliner, 1978). For example, establishing specific contingencies following completion of academic work can strengthen academic engagement. These contingent activities may include free time, access to desirable activities, public feedback about performance, and feedback to parents about the quality of student academic work during the school day. Altering some of the factors related to academic engagement can help ensure high rates of active, productive student involvement throughout the learning process (Fuchs, 1986).

Classroom Management

Another important part of assessing the classroom environment involves the examination of classroom management. Disruptive or inappropriate behaviors, such as misbehavior, out-of-seat, talking or looking around, are examples of competing responses that must be eliminated or minimized to enhance the learning environment. In fact, a student's achievement is often decreased by classroom noise and distractions. Effective classroom management can reduce disruption and increase the amount of allocated time for instruction. Three factors of effective classroom management are the use of classroom rules, sufficient transition time, and the efficient physical arrangement of the classroom.

There are at least two important reasons to use consistent classroom rules. First, rules help communicate the teacher's expectations regarding student behavior in the classroom. Secondly, rules provide an opportunity for students to receive attention from teachers for observing the rules (Paine, Radicchi, Roselinni, Deutchman, & Darch, 1983). In fact, rules can be established for different activities or desired behavior, such as social conduct (e.g., in your seat, work on assigned task, raise your hand before speaking), academic performance (e.g., 90% or more correct for a passing grade or to earn a reward) or instruction time (e.g., keep your hands/feet to yourself, talk only when it is your turn). When developing rules, Paine et al. (1983) offer the following guidelines: (a) use only three to four rules for any given activity, (b) keep wording of rules simple, (c) state the rules positively, (d) use different rules for different situations (e.g., transition time versus group instruction), and (e) post the rules in a prominent location in the classroom. Consistent implementation of classroom rules decreases disruptions (i.e., less noise, out-of-seat behavior, time off-task) and increases allocated time.

Transition time, another aspect of classroom management often overlooked when assessing the structured environment, is the amount of time it takes to change from one activity to another. The effective use of transition time leads to fewer student behavior problems during unstructured time. Clearly stated and implemented procedures for transition time can help minimize the amount of nonacademic time that children spend in school. It provides teachers with more time for academic instruction and decreases the number of behavior problems that often occur during this unstructured time (Paine et al., 1983). Therefore, the effective use of transition time can maximize allocated instructional time and minimize distractions which can indirectly influence academic performance.

The classroom's physical arrangement, defined as the organization of classroom space (i.e., furniture, teaching activities area, room dividers), can also have an effect on student behavior and academic performance. Ideally, this physical arrangement should facilitate optimum student performance. For example, classrooms in which desks are grouped together often have a higher incidence of student talking, which can indirectly affect a student's time spent on-task. Properly organizing classroom space can improve the level and quality of student interactions. Undesirable student interactions, such as excessive talking, can be decreased by separating the desks, while effective classroom arrangements can increase desirable student interaction. For example, open areas within the classroom can help facilitate student participation in a variety of activities in order to develop creativity, sharing, communication, and friendship skills. Factors such as the location of students' and the teacher's desks, classroom partitions, and the placement of teaching materials and stations can all play an important part in classroom management and the effectiveness of student learning (Paine et al., 1983). For example, student desks should be separated in rows, facing the chalkboard (not the window). Classroom partitions can help structure small-group instructional activities to minimize distractions from the rest of the class. Teaching stations can be positioned in any unoccupied corner of the room, whereas self-correction stations can be placed against one wall with a few tables or chairs. Materials stations can be placed in the front of the room for easy access in distribution or collection.

Within the classroom environment, teacher attention is probably one of the most powerful ways of managing a student's behavior. Teachers who provide attention or acknowledgment for appropriate task behaviors increase the probability of a student demonstrating that behavior in the future (Bernhard & Forehand, 1975; Broden, Bruce, Michelle, Carter, & Hall, 1970; Kazdin & Kloch, 1973). Teachers can positively affect academic performance by providing praise for on-task behaviors. Likewise, problematic behaviors, such as looking around and off-task behaviors, can also be maintained by contingent teacher attention. Therefore, teachers' attention can enhance academic acquisition, as well as decrease problematic behaviors, by providing frequent, brief contacts to students who are on-task. The use of modeling and teacher feedback (verbal or written) can also affect the accuracy of completed work. Error correction procedures, provided immediately upon completion of work, can increase academic performance and minimize future errors. Therefore, it is important to consider teacher attention and feedback to the target student when examining the academic ecology (Paine et al., 1983). Methods for assessing classroom variables are found in Table 2.

Instructional Practices

The last broad category of variables to assess in the structured academic environment is the instructional practices related to student outcomes. Practices such as planning procedures, teaching procedures, and monitoring and evaluation procedures can affect a student's achievement. Academic achievement requires students to learn and progress through

the curriculum at the expected pace. Students who have academic difficulties, however, are often unable to meet the curricular demands. In fact some educators believe that the curriculum pace moves too quickly for these students, in relation to their repertoire of skills. This creates a downward spiral in which these children get further and further behind academically (Gickling & Havertape, 1981).

Instructional material can be altered to ensure that a particular level of success is experienced (Dickinson & Butt, 1989). Gickling and Havertape (1981) suggest that the delivery of instruction can be altered to carefully control the difficulty level of curriculum materials. They recommend an instructional match be based on the student's performance rather than the chosen type of assignments. They have suggested three levels of instruction that represent the degree of instructional match or mismatch between the student's skills and the learning demands of the instructional task. If an assignment is entirely too challenging or at a frustrational level for a student, the ratio would approach 0% known items to 100% unknown items. An assignment far too easy or at an independent level would approach a ratio of 100% known to 0% unknown items. Student's daily performances are based on a continuum between these two extremes (Gickling & Havertape, 1981). Therefore, a student's performance can also be objectively measured via curriculum-based measurement procedures to determine the effectiveness of a teacher's instructional decisions, and the instructional ratios can be readjusted to maximize a student's academic progress (Gickling & Thompson, 1985).

Based on this assumption, they suggest that students acquire and retain new materials best if the ratio of known to unknown items are controlled while students are learning. Known responses are emitted rapidly and correctly all the time, whereas unknown responses are defined as either errors or hesitant responses. They recommend that instructional ratios for comprehension be 93–97% known to 3–7% unknown. Under conditions of drill and practice, however, instructional levels should contain 70–85% known and 15–30% unknown material. For example, students trying to learn 10 new vocabulary words should receive 8 known words and 2 unknown words or an instructional ratio of 80% known to 20% unknown or 8:2 (within Gickling's suggested ratio for drill and practice). Presented items exceeding these limits would be viewed at an independent level (e.g., 90% known to 10% unknown or 9:1 — too easy), while material below these levels would be considered to be at a frustrational level (e.g., 20% known to 80% unknown or 2:8 — too difficult). Since instructional mismatch is often a major contributor to the poor academic performance of low-achieving students, assessment procedures need to evaluate and, if necessary, alter the match between student acquisition and instruction.

In addition to matching a student's skill and instructional materials, other variables that enhance learning and influence a person's learning of new ma-

terial involve practice, temporal continuity, and cumulative versus rapid material presentation (Gleason, Carnine, & Vala, 1988; Johnson, Gersten, & Carnine, 1987). An important consideration regarding acquisition of new material is the time delay between learning and reviewing difficult items. Although students may learn difficult information, they may not have ample opportunities to review this newly acquired information. If a student is taught a word but does not have subsequent chances to practice, this may impede the rate of learning. A delayed review may also increase the likelihood that mistakes will occur in the future. To minimize possible future errors, students should review difficult material within a day or two of initial learning. Ysseldyke and Christenson (1987a) also highlight the following requirements for providing relevant practice opportunities: (a) assignment of practice tasks at an instructional level appropriate for the student (i.e., instructional levels mentioned by Gickling and his associates for drill and practice — previously discussed), (b) modification of task requirements when necessary so that a student can complete the work successfully, (c) careful monitoring of student performance, and (d) frequent feedback during practice. Furthermore, opportunities for practice should be implemented until a student makes only infrequent mistakes.

Teacher planning and evaluation is another important instructional practice related to learning. Teachers who set discrete academic performance goals for remedial students and collect periodic data on student progress are able to affect greater achievement (Fuchs, Deno, & Mirkin, 1984). Ongoing progress evaluation facilitates formative modification of instructional procedures. Self-management techniques, such as self-charting, self-monitoring, self-evaluation, and contingency contracting, can also increase academic performance, and, therefore, should be considered when assessing the academic environment (Ysseldyke & Christenson, 1987a). Suggested methods for assessing instructional variables can be found in Table 3.

SUMMARY

Analyzing the relationship between student characteristics, environmental variables and instructional practices is crucial to understanding students in a structured classroom environment. It enables psychologists to determine the interaction between these variables and the presenting problem. Furthermore, predictions about classroom events and student performance can help determine appropriate intervention strategies for academic success. Alternative strategies, such as interviewing, direct observations, analysis of permanent products, CBM probes, and treatment evaluation, allow psychologists to directly assess and remediate academic skills. These direct methods not only provide intervention strategies, but also offer ways to evaluate the success of treatment programs. Therefore, the alternative service delivery model discussed in this chapter links assessment to intervention to provide an understanding of the relationship between environmental factors that impact student performance.

ANNOTATED BIBLIOGRAPHY

Graden, J. L., Zins, J. E., & Curtis, M. J. (1988). *Alternative educational delivery systems: Enhancing instructional options for all students.* Washington, DC: National Association of School Psychologists.

This is an excellent source for information on alternative service delivery in psychology. The book is organized into three

major parts corresponding to the need for alternatives, information on possible alternative frameworks, and means of facilitating the change process to implement alternative service delivery systems. Alternative practices related to referral, assessment, and intervention as well as an alternative organizational framework for providing a broad-based service to school and district levels are discussed. It also covers special topics relative to alternative services for individuals with severe disabilities, infants and toddlers, and preschoolers.

Paine, S. C., Radicchi, J., Rosellini, L., Deutchman, L., & Darch, C. B. (1983). *Structuring your classroom for academic success.* Champaign, IL: Research Press Company.
This book provides guidance in managing the classroom successfully. It presents an overview of important variables related to management skills. The authors' recommendations are based on empirical research and teacher experiences. Overall, the book is a valuable resource for psychologists and can serve as the basis for inservice teacher training programs.

Shapiro, E. S. (1989). *Academic skills problems: Direct assessment and intervention.* New York: Guilford Press.
This book provides methods for direct assessment and intervention of academic problems. It is written with the practitioner in mind and offers step-by-step instructions for using these methods. In particular, procedures for direct observation and curriculum-based assessment procedures are discussed and forms for many parts of the evaluation process are included in the book.

Zins, J. E., Curtis, M. J., Graden, J. L., & Ponti, C. R. (1988). *Helping students succeed in the regular classroom: A guide for developing intervention assistance programs.* San Francisco: Jossey-Bass, Inc.
All the ingredients for understanding and effectively implementing and operating an intervention assistance program in the schools are presented in this book. They present a practical yet necessary conceptual background to understand the intervention assistance process. Sufficient detail is also provided to enable practitioners to make intervention assistance programs an integral component of a psychologist's current educational system. Additionally, the development of interventions for individual students as well as the implementation of intervention assistance programs in the school organization are discussed.

Best Practices in Developing Local Norms in Behavioral Assessment

Andrea Canter
Minneapolis Public Schools

The use of local norms in the assessment of academic skills has received considerable attention in recent years, particularly in the professional literature regarding Curriculum-Based Measurement. This chapter addresses the application of local norms to the assessment of social and functional skills. An overview will be followed by a discussion of basic considerations in the development of locally normed procedures, recommended practices, and a case study of the development of a locally normed functional skills assessment procedure at the district and state level.

OVERVIEW

For nearly a century, the practice of school psychology has been characterized by nationally normed assessment procedures used to diagnose and classify intellectual, academic, and behavioral problems. In recent years, researchers and practitioners have implemented significant alternatives to traditional approaches for measuring academic skills, such as Curriculum-Based Assessment and Curriculum-Based Measurement. This new generation of direct assessment procedures is more strongly linked to intervention than to classification, more relevant to instruction than to diagnosis, and more tied to local than to national standards of performance.

While the call to *replace* traditional approaches with alternative models is the source of much controversy in the profession (e.g., Braden & Reschly, 1993), the development of direct assessment and other new procedures has unquestionably resulted in improved professional practice linked to students' academic outcomes. The shortcomings of traditional assessment are certainly as evident in the domains of social and adaptive behavior as in the domains of cognition and achievement: Student performance is compared to statistical national norms regardless of relevance to local cultural norms and home/school expectations and without a direct link to intervention.

A Rationale for Local Norms

One alternative approach to traditional assessments is the use of local, rather than national, norms. Local norms have been cited as essential to developing instructionally and ecologically relevant assessments (Bardon, 1988), as more realistic and, for some purposes, as more appropriate than "nonequivalent national norms" (Anastasi, 1988). Locally normed measures provide a means of overcoming some of the criticisms of traditional procedures, as they can address social standards and environmental contexts, lead to intervention, and reduce ethnic and cultural bias. Local norms also can provide an essential perspective to the special education eligibility and placement process as they "operationalize the expectations of the mainstream environment" (Shinn, 1989).

Even within the context of traditional assessment purposes of diagnosis and classification, the use of a local frame of reference is essential in addressing functional and social skills which are typically defined in terms of social significance or social validity. Recognition of the social significance of behavior has been recommended as a component of state definitions of emotional/behavioral disorder (Cullinen, Epstein, & McLinden, 1986). Gresham (1983) defines social skills as "situationally specific behaviors that predict important social outcomes for children and youth."

To best understand the student's functioning, one must consider the social norms or expectations of the classroom, school, and community in which the student is asked to perform. In fact, Achenbach, McConaughy, and Howell (1987) cite the situational specificity of behavior, rather than measurement error, as the basis of relatively low inter-rater reliability of behavior scales. Deno (1989) notes the importance of situational specificity in understanding the concept of "handicap."

656

> *Handicaps can only be defined in terms of the relationship between what a person can do and what a person must do to succeed in a given environment. . . . Teachers do not make judgments . . . based only on the universal norms of the culture; instead, their judgments are also based on the behavior of the students in classrooms and schools within which they are working.* (p. 5, 10)

Local Norms, Expectations, and Intervention

The concept of social validity is closely tied to local expectations — the standards of one's community, culture, neighborhood, school, or peer group. National norms provide information about the individual's functioning relative to what are assumed to be universal standards. Yet, in a diverse society, such assumptions can lead to cultural and regional bias in measurement, one of the strongest criticisms of norm-referenced testing.

Locally developed norms, on the other hand, should reflect what is relevant for success within the local context; procedures reflecting local standards should more fairly identify individuals in need of intervention in order to perform successfully. Such measures directly relate to referral concerns, as teacher referrals likely reflect a discrepancy between student performance and teacher *expectation*, rather than an absolute deficit in skills (Ritter, 1989; Shinn, Tindal, & Spira, 1987). Furthermore, congruence with teacher expectations for classroom functioning is highly related to mainstream success for at-risk students and those with disabilities (Hersh & Walker, 1983).

Assessment approaches reflecting local standards are more readily applied to designing intervention strategies than are global, nationally normed procedures. Such procedures allow comparison of a referred student with relevant peer groups, facilitating informed decisions regarding (a) the most appropriate and least restrictive placement, (b) the degree of discrepancy between the student's behavior and the expectations of a potential placement, and (c) areas requiring intervention prior to transition to a less restrictive or mainstream placement.

These characteristics are consistent with the concept of "template matching" described by Hoier, McConnell, and Pallay (1987), in which assessment information is used to develop a "template" (behavioral profile) of individual classrooms. When the situational specificity of student performance is measured and understood, intervention strategies can better focus on generalization across settings. Thus, assessment based on local standards can help to promote successful transitions from special to regular education classrooms (McConnell, 1987; Horn & Fuchs, 1987) as well as successful inclusion efforts.

Importance to School Psychology Practice

School psychologists are generally trained to serve as problem solvers, yet traditional practice tends to emphasize problem *identification*. School psychologists seeking expanded roles should find that the implementation of locally normed assessment procedures enhances opportunities for problem-solving consultation by directly addressing teacher expectations and referral concerns. By offering alternative or supplemental information which can be interpreted in the local cultural context, local norms also can help alleviate ethical dilemmas created by the potentially discriminatory nature of nationally normed procedures. Furthermore, the design and development of locally normed procedures provides an ideal opportunity for school psychologists to use their training and expertise in measurement and applied research within the practical scope of a single classroom, school, or district.

Limitations of Local Norms

Use of local norms is hardly a cure for all problems associated with traditional measures. Many of the criticisms of nationally normed tests apply to local norms as well. A norm-referenced measure of any sort may not fit the assessment purpose; even a locally normed procedure may not fairly represent a given individual; technical adequacy can be a significant problem with locally normed procedures if samples are small. If the behaviors measured vary significantly across settings, it may be difficult to identify sufficiently consistent environments from which to draw an adequate sample for norming purposes. Furthermore, when data reflect local values and/or local samples, one can not generalize with much confidence beyond the immediate context.

BASIC CONSIDERATIONS

To effectively design and implement a locally based assessment model, the school psychologist must consider a number of factors, including (a) the purpose of the assessment procedure(s); (b) the "measurement net" or domain(s) of the assessment; (c) the definition and characteristics of the local population; (d) the format of the assessment; (e) data collection procedures, including standardization and psychometric properties; and (f) the availability of administrative and technical support for the design and implementation of the procedure. These factors are addressed sequentially, as presented in Figure 1.

Purpose of Assessment

Prior to embarking on the development of a locally normed assessment procedure, school psychologists should determine the reasons why the measure is needed and the level of inference to be made from

the data. In designing the measure, educators need to consider:

- What referral concerns/school problems will the measure address?
- What types of educational decision (eligibility, placement, instructional strategies) will be made?
- What level of decision making is desired (e.g., screening versus diagnosis)?
- Is a new tool needed or just local norming of an existing measure?

For reasons just noted, locally normed procedures are well-suited for the assessment of social and functional behaviors, as these are frequently situation-specific and tend to reflect localized cultural and community values and expectations. Normative measures typically are most appropriate for identifying, classifying, and sorting individuals, and are less often appropriate for specific intervention planning or progress monitoring.

The use of locally normed measures enables school personnel to directly address the *need* for special services as well as *eligibility*. If most students in a third-grade class are unable to independently exhibit social problem-solving skills and all score below the 25th percentile on a nationally normed scale of social skills, John's "below average" performance on that scale will not be regarded as discrepant from his classmates. Rather than identify all as in need of remedial or special education, as might be indicated using nationally normed tests, the locally normed procedure indicates that John is functioning like his classmates or is meeting most of the demands of his current class placement. However, if John's areas of deficit are dissimilar to those of his classmates, some type of intervention would be warranted to enable him to meet the expectations of his teacher and to avoid referral for more restrictive programming.

Is the procedure intended to serve as a screening device, with students who fall below some set criterion to be referred for more in-depth assessment? Or is the procedure intended to be used to make placement/programmatic decisions? Local norms can be appropriately applied to both purposes, but should not be used in isolation to make diagnostic decisions or special placements. Locally normed measures can help limit the number of students for whom more complete diagnostic information will be obtained by sorting out a group who appears to be at risk relative to the typical students in the local population. Both absolute and relative performance data should be obtained prior to making placement decisions.

Depending upon the format and content of the procedure, some locally normed measures may be appropriate for program planning, with the normative data serving as a "benchmark" or criterion level of performance. Students who fall below this benchmark might be identified for intervention. For example, if most fifth graders are able to use a problem-solving approach to resolving peer conflict, those who are rated low on this skill might be referred to a conflict resolution program.

Generally, norm-referenced measures can not be repeated at frequent intervals to measure progress or response to intervention. At annual intervals, or perhaps twice per year, teacher ratings of a student's skills on a locally normed scale might provide useful data regarding the degree of discrepancy between a student and his peer group following implementation of intervention services.

The "Measurement Net"

In a problem-solving model, educators develop questions which the assessment will attempt to answer. Questions which might be appropriately addressed by a locally normed measure of social/functional skills include:

- How do the student's social skills compare to those of her classmates?
- Are the student's deficits in areas where staff expectations are high or low?
- Has the student's relative performance of locally desired social skills improved following the social skills group training program?

The assessment tool must address the behaviors/skills relevant to the question or problem area. Using the examples just listed, "social skills" is the apparent domain of concern; to find answers, both the skill level of the referred student and the expectations of school staff must be addressed by the assessment.

Whatever the area of concern, the skills or behavior of that domain must be clearly defined and adequately sampled within the boundaries of the measure's intended purpose. What skills and behaviors will be included in "social skills?" Is an in-depth, task-analyzed sampling of these skills needed or will a more superficial sampling of general skills suffice? Are multiple skill areas (domains) needed, such as adult-directed interaction versus peer-directed interaction, or will a single domain such as interpersonal interaction be adequate? Decisions in regard to these questions will help determine the content and length of the measure.

Shinn (1989) describes the establishment of a "measurement net" to identify specific skills to be included in locally normed measures. A pool of possible skills/test items is generated by requesting information from teachers and surveying available curriculum and research literature. Surveying teachers regarding the behaviors of typical, successful students versus unsuccessful students will provide a starting point for developing a school- or classroom-based behavior rating scale. A review of the objectives of a social skills training curriculum will also contribute tasks/skills to the measurement net. This pool of potential items can then be reviewed by teachers and others, and field tested prior to final decisions regarding the content of the measure. A similar approach can be taken when considering local norming of an existing test or scale; review and piloting will be necessary to determine if the tool's content has local relevance.

Defining the Local Population

Who will be the subject of the assessment? Generally, one considers developing local norms or new locally normed procedures because some or all of the population of concern is inadequately served by existing norms and measures of the relevant behavioral domains. Defining the "local" population is critical. If a fair measure of the adaptive behavior skills of Native American students is desired, it would make little sense to randomly sample from the entire school population in a district of only 12% Native American students: The new norms would still reflect a very limited number of the target group. If the target group is "urban midwest children," then the normative group might be randomly drawn from an entire midwest, urban district.

Some behavioral concerns are so situationally specific that the target population appropriately is an individual classroom or school building. Even in situations where the behavior may have more generalized consequences, *intervention* may be most appropriate when it addresses skills needed in the immediate environment of the classroom. Therefore, it would be appropriate to use the typical behavior of students in that classroom as the standard for comparison, rather than the behavior of students in the school or district as a whole.

Defining the population to serve as the "standard" is critical to the design of the measure, to the development of reliable and valid norms, and to the ultimate usefulness of the measure as a problem-solving tool.

Appropriate Formats for the Assessment

The format selected for any assessment tool must be appropriate for the assessment's purpose, desired domains, and target population. In behavioral and functional skills areas, observation is often the most practical direct assessment approach; indirect methods such as checklists and rating scales are commonly used and more easily developed at the local level than standardized individual tests. Rating scales can serve as criterion measures and/or as normative measures in behavioral and functional assessments. While third-party data is inevitably vulnerable to some subjective judgment, parent and teacher ratings of specific behaviors can be highly reliable and valid (e.g., Gresham, 1981; Hersh & Walker, 1983). When developed and normed locally, such procedures reflect the community standards and expectations for performance.

An alternative means of establishing local norms is to obtain ratings of expected or preferred performance rather than the direct ratings of individuals from a representative sample. For example, instead of rating the social behaviors of 10 "typical" or randomly selected students, a sample of teachers would be asked to rate the importance or desirability of those social behaviors as related to classroom success. Referred students' behaviors would then be rated and compared to the established expectations for that school or district; this approach could also be limited to one classroom and one teacher's expectations. While teacher expectations are not necessarily realistic or consistent with the rated behaviors of "typical" students, these expectations tend to be stable over time and are highly related to referral to special education (Hersh & Walker, 1983).

Once the type of measure is determined, the specific format must be considered. Rating scales, for example, can require yes/no responses, ratings of the frequency or severity of problem behavior, or ratings of the degree of independence or success of the individual's performance. The specificity of the ratings and format for responding will vary with the level of inference desired in relation to the scale's purpose: Psychologists must seek the most practical balance between precision and user-friendliness.

For the purpose of classification or screening for more detailed assessment, the most simple and global ratings may be sufficient. However, for intervention planning, effective measures typically differentiate deficits in skill versus deficits in performance (Gresham, 1984). Multipoint rating scales more reliably reflect important differences in the frequency and quality of target behaviors compared to dichotomous scales (Edelbrock, 1983), although complex ratings can be overly demanding for the rater and possibly limit the usefulness of the results. Furthermore, highly demanding rating tasks could significantly reduce the level of cooperation needed for data collection.

Similar considerations apply to the development of standardized observational systems from which local norms are derived. Complex coding procedures may yield more specific data but also require extensive training for reliable use. Systems commonly used in research may be unnecessarily complex for classroom implementation and the intended level of decision-making.

Data Collection

Developing local norms requires careful consideration of the level of technical adequacy needed for decision-making. Special education labelling and

BEST COPY AVAILABLE

placement have obvious long-term implications for the student, and a higher level of technical confidence is necessary than in the case of screening. The general considerations of reliability and validity of norm-referenced procedures apply to the development of locally normed measures. It is typically impractical, however, to hold locally normed measures to the same standards of technical adequacy used to judge nationally normed procedures. Generalization from locally normed data should address inherent limitations of smaller samples, restricted sampling procedures, and situational specificity.

Local norms should appropriately reflect the population of concern, be it a classroom, school building, or school district. The standardization sample should have proportionate representation according to relevant demographic factors such as age, grade, gender, economic status, and ethnicity. Depending upon the tool's purpose, students with disabilities may or may not be appropriately included in normative samples. If norms are desired for the entire school district, adequate geographic representation is necessary, as well as sampling across the various curricula and organization options present in the district. Particularly when the norms are to be derived from a single classroom or grade level, the normative group might include all students from that population rather than a random sample.

What norms will be available for the interpretation of results? Separate norms for groups known to differ significantly on the target behaviors are preferred for classification and placement purposes, but collecting sufficiently large samples for multiple norming groups is often impractical. Age or grade-level norms tend to be the easiest to construct, assuming that development is a significant factor. Some problematic and social behaviors do not appear to be highly related to age within the school population; gender-specific norms may be more appropriate for some behavioral domains. Ethnic group norms may also be desirable for some purposes, but often the smaller cultural groups can not be adequately sampled within a school or district.

What type of normative scores are desired? Percentiles are often the easiest scores to report and interpret, but eligibility criteria often require the use of standard scores. Standard scores can be derived from any distribution, but distributions significantly skewed away from the normal curve yield standard scores that can be misleading.

Sample sizes will dictate reliability of norms and generalizability to similar students in the population. Obviously, larger samples should be more reliable than smaller samples, but how large a sample is necessary for the purpose of the procedure? If percentiles are desired, measurement experts generally recommend that at least 100 individuals be included in each comparison group (e.g., each grade level) so that "true percentiles" can be derived. Smaller groups require "smoothed" percentiles using linear interpolation in order to determine values at each percentile point. Groups of less than 100 may nevertheless yield useful norms if sampling is conducted carefully, but the scores should be interpreted with greater caution.

It clearly is impossible to determine true percentiles for single classroom samples, and groups of 25 to 30 students will certainly not yield the stable normative data possible with significantly larger groups. However, means and standard deviations can be derived and used for screening, planning, and evaluating student progress at the classroom or building level. Such samples can be used effectively for screening purposes and can serve as a practical alternative approach for developing classroom norms for each class or grade level in a school. Samples of 5 to 10 typical students from each classroom can serve as a standard for comparison with referred students in order to obtain a gross estimate of deviation from the norm. Such data can help teams prioritize referral for more extensive assessment or serve as a first-level screening to identify students for intervention. Depending upon the type of measurement, small classroom samples may offer the only practical means of collecting normative data without external funding resources.

Initial piloting of a new measure or new norming procedure with small classroom or building samples may be desirable even if the ultimate goal is district-level norms: The smaller investigation provides a cost-effective means of field-testing materials, procedures, scoring, and decision making. Small investigations can also be effective in establishing teacher expectations as a practical alternative to true norms.

The collection of normative data should, to the extent possible, include data regarding internal consistency, stability of results, and validity relative to the assessment purpose. Depending upon sample size, some or all of the sample can serve as a test-retest group. Appropriate criterion measures, such as similar scales or class grades, can be included to examine concurrent and predictive validity. Less formal procedures, such as referral rates, placement rates, and observed response to intervention, can also be useful in validating local norms. With sufficiently large samples, statistical tests of discriminant validity can be applied to determine if the locally normed procedure adequately differentiates groups of students for eligibility or treatment purposes.

When developing normative observation systems and third-party rating scales, one must consider inter-rater agreement. Typically this is determined by comparing the results of two independent observers/raters, such as teacher and parent, reading teacher and math teacher, or two trained observers making simultaneous observations. Behavior scales are often criticized if inter-rater agreement is only moderate. However, if the target behaviors are assumed to be situationally specific, a high degree of inter-rater agreement may not be realistic; in fact, differences between raters may be of both diagnostic and prescriptive value. Some assessment systems are designed to obtain two or more sets of ratings or observations of the same student in order to provide such comparisons. The degree of acceptable inter-rater difference will of course depend upon the purpose of the assessment and level of inference desired.

Administrative and Technical Support

The development of local measures and local norms is typically carried out by school district personnel, such as school psychologists, sometimes with the assistance of grants and in collaboration with university researchers. Regardless of the scope of the project, individuals developing these procedures need the support of school administrators. Professional time must be allocated to the project, and the project must thus be
regarded as a priority among the many tasks of the school psychologist. The administration must therefore understand and support the rationale for developing local norms and perceive the proposed project as a cost-effective means of impacting student outcomes.

General support from the school district administration is an essential first step, but support from building principals is critical to implementing data collection. Parents and teachers will ultimately be involved in data collection, either directly by responding to rating scales or administering tests, or indirectly through the consent process. The endorsement and cooperation of the building principal will help to secure the cooperation of parents, staff, and students, and lend credibility to the project. However, directives from administrators are not sufficient to ensure cooperation of subjects and respondents. Teachers and parents must also perceive that the project leads to better services for students and involves minimal time, effort, and disruption of the normal school routine.

Finally, to implement and successfully complete a local norming project, the school psychologist needs access to sufficient technical support. Very small studies (such as classroom norming projects) may require minimal clerical support, data entry, and data analysis. Larger scale projects such as district-wide norming may require additional funding (such as grants) to secure computer time, data entry personnel, consultants with statistical expertise, and, in some cases, data collection personnel.

Large school districts often have research departments with adequate support for such projects, while smaller districts may have to seek (and purchase) expertise elsewhere. Local universities often offer opportunities for collaboration, shared computer access, and pools of inexpensive labor for data collection.

When external funding is needed, local sources often offer the best opportunities for relatively small grants. State departments of education, local corporations, and private foundations often provide grants for projects directed toward at-risk and special needs populations. Larger school districts often employ one or more individuals to identify such funding sources and to assist staff in applying for grants.

Implementation Issues

The final step in establishing local norms is the development of an implementation plan. The plan should address relevant timelines for training staff in the new procedure(s), a system of monitoring the use of the procedure(s), and methods of evaluating the impact of the procedure(s) in the context of the assessment's intended purpose. Monitoring can be accomplished through periodic surveys or reporting systems which help determine if procedures are appropriately followed. Depending upon the assessment's purpose, evaluation plans might address referral and/or placement rates, impact on decision making, teacher satisfaction, and so forth. If resources are available, evaluation might also include validation through discriminant analysis and replication studies.

BEST PRACTICES

The development and implementation of a locally normed assessment procedure unfolds as a problem-solving approach to decision making (see Figure 1). At each step, the school psychologist is confronted with questions to answer in order to best shape the final product (measure) to the needs of the classroom, school, or district. Regardless of the domains of behavior measured or of the type of measure developed, this sequence of decisions allows the school psychologist to adapt the assessment tool to the identified needs, local population, and available resources.

For the purpose of this chapter, this decision-making sequence will be described in the context of a case-study illustration (Figure 2), using as the example the development of the Mainstream Survival Skills Assessment (MSSA, Canter & Heistad, 1990). While the MSSA is a multimethod system addressing functional and social behavior through ratings, observation, and interviews, this discussion will include only the locally normed rating-scale components.

chologists and other team members are frequently confronted with dilemmas resulting from gaps in assessment technology. One such problem encountered repeatedly during the mid-1980s was the apparent discrepancy between the behaviors which prompted special education referral and those behaviors which our available tools were designed to assess. Furthermore, recent changes in state and federal rules mandated assessment of adaptive behavior in school as well as home/community settings as part of the identification of "mental handicaps"; yet there were very few measures published and none appeared to be specifically relevant to the diverse local population. During the 1986–87 school year, school psychologists in a midwest urban school district initiated a project to address this gap in technology through the development of a local assessment procedure.

After reviewing literature and informally surveying local teachers regarding factors related to school success and failure, "school survival skills" were identified as the general target behaviors for the new assessment. Researchers have described as "survival skills" task-related behaviors such as academic engagement, following directions, seeking assistance, and organizing materials, as well as functional academic, personal, and social competencies (Cobb & Hops, 1973; Hops & Cobb, 1974), and have found these skills to effectively differentiate successful from nonsuccessful mainstream students (McConnell et al., 1984). It was therefore hypothesized that assessment of school-based functional skills would contribute important data to classification and placement decisions, to predicting student outcomes in alternative settings, and, subsequently, to promoting the development and implementation of curricula to improve survival skills for all students.

It was highly desirable that the procedure be sufficiently robust to be useful in eligibility decisions and that student performance be readily compared to teacher expectations.

Establishing the Measurement Net

- *What skills and behaviors will be assessed?*

After defining the generic set of target behaviors as "school survival skills," the next problem facing scale developers was identification of the specific skills, tasks, and behavior to be measured. The overriding criterion for inclusion in the "net" was the relationship of the skill to successful and independent functioning in mainstream classrooms and to available remediation/intervention strategies. Furthermore, it was essential that the skill was readily observable in school and classroom environments.

In addition to an extensive review of relevant literature on the behavioral correlates of school success and failure, K–8 teachers from a sample of local schools were surveyed regarding their expectations and observations. Currently available measures of functional and problematic behavior were also reviewed. From these sources, a preliminary set of skills was generated and reviewed by a panel of teachers (regular and special education), school social workers, and school psychologists. These skills were then organized into four (and later condensed into three) general domains of functional academics, task orientation, personal independence, and social skills.

Defining the Local Population

- *What student population(s) will be the target of this assessment procedure?*
- *Who will be included in the normative sample?*

The assessment concerns which prompted this project were not unique to any one school in the district. Because 90% of the district's students were bussed for desegregation purposes, there was considerable heterogeneity across schools regardless of neighborhood differences. It was therefore desirable that the new measure be applicable district-wide.

After trying out items and discussing the procedure with teachers, it was decided to limit the scope of the measure to the elementary (K–6) population. Skills judged relevant for school success appeared to be acquired by fifth or sixth grade; for adolescents, vocational interests/skills and a very different set of social expectations appeared relevant, making a K–12 tool impractical.

It was also decided to include representative samples of *all* district students who participated in mainstream programs, including those with mild disabilities and with Limited English Proficiency. Of critical importance was a representative sampling of the district's nonwhite ethnic populations, who at that time accounted for nearly half of the total enrollment. Similarly, it was important that the district's economic diversity be reflected in the norming sample.

Because the measure was to be used district-wide, students from every K–6 school in the district were included in the normative sample, ensuring geographic representation throughout the city as well as sampling across all organizational and curricular structures in the district, such as open and "magnet" schools.

Research and test development regarding the construct of adaptive behavior, including socialization, indicated a strong relationship between these skills and age across the school years. Norms for each grade level were therefore necessary for the MSSA. Reviewing the enrollment records of many students indicated that there was often an age range in excess of 18 months in any given classroom. Therefore, norms for *age* groups as well as grade levels were desirable. While gender-specific norms are often included with nationally normed measures, developing gender norms for the MSSA would require doubling of the size of each age/grade sample, an impractical consideration given available resources. However, gender differences were to be studied to help interpret results.

Determining Appropriate Formats

- *What is the most cost-effective means of measuring target skills, in the context of available resources, population needs, and assessment purpose?*
- *What format will minimize resistance to data collection?*

For both the purpose of cost-effective test development and the ultimate goal of implementing a practical data collection procedure, a rating-scale format was selected, using a three-point scale reflecting independence in typical functioning. Two forms of this rating scale were devised — one for teachers to rate an individual student's competencies, and a second with identical items for teachers to rate the skills' importance to classroom success. The teacher rating scale would provide normative data relative to other district students. The teacher expectations scale would provide a template for that classroom, which could then be compared to an individual student's skills for the purpose of identifying intervention targets or matching students to potential environments. Scale items were written as positive descriptors based upon the list of skills established earlier for each domain.

Designing Data Collection

- *What level of technical adequacy and representative sampling is acceptable for the purpose of this assessment procedure?*
- *How will appropriate samples be obtained?*

The MSSA rating scales followed traditional test-development procedures, including experimentation with item content and format (pilot testing), standardization with a random sample of mainstream students, tests of reliability and validity, and discriminant analyses using special population samples. Published scales of similar behaviors were reviewed to determine a range of acceptable sample sizes, reliability, and validity data.

The normative sample was derived through random sampling of each elementary school's enrollment lists, including a number of students proportionate to that school's contribution to the total district enrollment. Because of the desegregation efforts across the district, it was assumed that random sampling at each grade level at each school would yield a total sample representative of the district in terms of gender, ethnicity, socioeconomic status (SES), and disability. To obtain the desired target samples of 100 students per grade level, samples of 140 to 150 were selected for the norming pool. Subsamples of this total were included in test-retest reliability (second grade), interrater agreement (using students in team-teaching situations), and concurrent validity (third grade) samples, using the Vineland Adaptive Behavior Scales, Classroom Edition as the criterion measure.

Discriminant validity samples were drawn from special education enrollment lists of students in resource and self-contained classroom programs for children with mental handicaps, learning disabilities, and emotional/behavioral disorders. Another sample was selected from the Limited English Proficiency program.

The original rating scale included 138 items in four subdomains. Following statistical analyses of the normative data, 20 items were discarded for failing to meet criteria of developmental validity (correlations with age), discriminant validity (differentiation of disabled versus nondisabled students), reliability (internal consistency or test-retest), or social validity (ratings of importance by teachers). The 50 items with the highest concordance with these criteria formed the teacher expectations scale. A sample of district teachers at each grade level (K–6) was asked to complete the expectations scale.

Extensive analyses were conducted to examine age, gender, ethnic, and SES differences in teachers ratings, as well as to examine different special education samples. Norms tables were constructed using smoothed percentiles with linear interpolation for the final normative samples of 80 to 90 students per grade level.

Rationale, data collection procedures, norms tables, technical data, and recommendations for applying data to educational decisions were included in a manual published by the district for school personnel (Canter & Heistad, 1990).

Administrative and Technical Support

- *What resources (funding, personnel) will be necessary to support the desired technical design?*

Within the local district, many sources of support were tapped for this project. The Research and Evaluation staff included a school psychologist well versed in experimental design, data analysis, and computer technology. Psychological Services staff included an individual assigned half-time to research and evaluation projects. Principals and special education administrators expressed interest in the development of the MSSA and encouraged teacher participation. To accomplish the goals of the project in a timely manner, however, required additional funding for project coordination, teacher incentives (stipends for each scale completed), materials, and data entry. A proposal to the state department of education for funding as an innovative assessment project resulted in a grant of approximately $30,000.

Implementation Issues

- *Does the new procedure fulfill its intended purpose?*
- *What training and monitoring is needed to ensure appropriate implementation?*

The MSSA project resulted in a teacher-rating scale that meets accepted standards of reliability and validity and is in fact technically comparable to many published, nationally normed measures of adaptive and social behavior (Canter & Heistad, 1990). The norming population very closely reflects the demographic characteristics of the district, and, as predicted, ratings differentiated disabled from nondisabled and mildly disabled from more severely disabled students. As a contingency for securing funding, the MSSA was normed at the state level in a replication of the district-level norming project. This statewide study served to further validate the data obtained in the earlier project (Canter, Schrot, & Heistad, 1990).

The MSSA scales have been used extensively in the district as components of special education eligibility assessments and as fundamental data in planning interventions and placements for mildly disabled students who participate in inclusion programs or who are making the transition to less restrictive programs. To ensure appropriate implementation, numerous presentations have been made to school personnel, particularly to special education personnel. Over time, additional data have been collected to enhance understanding of survival skills relative to specific groups, including students with severe emotional/behavioral disorders, students with Limited English Proficiency, and Native American students.

As the local district moves toward adopting a problem-solving model to address academic and behavior referrals, the MSSA offers a locally normed behavioral complement to the academic procedures of Curriculum-Based Measurement (also locally normed) as well as to more traditional norm-referenced measures and direct observation systems which comprise the comprehensive assessment arsenal. Of particular value to the problem-solving model has been the comparison of teacher expectation ratings to teachers' ratings of referred students' performances. School psychologists have been able to identify targets for intervention that are specific to the interaction between the referred student and the classroom environment or to the potential interaction between the student and a future environment. Such interventions then become key to planning transitions to less restrictive settings or to developing skills necessary to maintain the student in the mainstream. At times, these data have also been used to help identify specific classrooms where students are most likely to succeed.

SUMMARY

This chapter has presented a rationale for the use of local norms and standards in the assessment of school-based functional and social behaviors, a set of basic considerations in the development of local procedures, and best practice guidelines using a case-study example. School psychologists are ideally suited to the roles of test development consultants and project coordinators: They possess knowledge of educational and psychological measurement and basic research design, as well as intimate knowledge of the purposes of assessment in education and of the gaps between our technology and student/teacher needs.

The use of local norms for identifying and understanding achievement problems has been promoted among researchers and practitioners, particularly regarding implementing Curriculum-Based Measurement strategies. The advantage of locally normed procedures for identifying and understanding behavioral and functional skills problems has been well-stated in the literature but appears to be less widely implemented in practice. Even very small projects at the classroom or building level can provide the local frame of reference necessary for appropriate identification of target behaviors which are essential to positive student outcomes.

Skills that are basic to daily functioning in significant settings must be identified, analyzed, and directly taught if students are to be ready for mainstream schooling and, ultimately, the demands of independent living.

Many published, norm-referenced procedures offer technical advantages over locally developed measures but rely upon national norms and assumptions of commonality in their criteria for success. There is no doubt that such general standards for performance should be considered in the assessment process. However, the importance of ecologically valid assessment to effective intervention can not be overstated. By including local standards and situationally specific performance criteria in the comprehensive assessment plan, school psychologists can help promote better practices in both problem identification and intervention for a broad student population.

ANNOTATED BIBLIOGRAPHY

Canter, A. S., & Heistad, D. (1990). ***Mainstream Survival Skills Assessment: Administration and technical manual*** (Minneapolis Schools Edition). Minneapolis: Minneapolis Public Schools.

This manual includes a review of relevant research, an extensive description of the process of developing a locally normed assessment procedure, and detailed technical data, as well as administration and interpretation guidelines. Age and grade norms tables for the rating scale are included. The companion manual (Canter, Schrot, & Heistad, 1990) describes the statewide replication project. (Both manuals can be obtained at cost [$10 each] from the Prescriptive Instruction Center, Minneapolis Public Schools, 807 N.E. Broadway, Minneapolis, MN 55413.)

Hersh, R. H., & Walker, H. M. (1983). Great expectations: Making schools effective for all students. *Policy Studies Review, 2*, 147–188.

Hersh and Walker examine components of effective schooling in the context of serving children with disabilities in the mainstream classroom. Their extensive literature review focuses on the expectations and standards of classroom teachers and on "social behavior survival" – preparing special education students for the realities of regular education.

Hoier, T. S., McConnell, S. R., & Pallay, A. G. (1987). Observational assessment for planning and evaluating educational transitions: An analysis of template matching. *Behavioral Assessment, 9*, 6–20.

This article reports an observational study of behavioral conditions in mainstream versus special education classrooms which can be linked to intervention. Of particular relevance to local norming efforts is the review of research regarding local contingencies which impact teacher and student behavior and the description of data collection methods.

Shinn, M. R. (1989). Identifying and defining academic problems: CBM screening and eligibility procedures. In M. R. Shinn (Ed.), *Curriculum-Based Measurement: Assessing special children* (pp. 90–129). New York: Guilford.

This chapter, while specifically addressing CBM procedures, has useful applications to the development of local norms in general. Shinn discusses the creation of the "measurement net," alternative approaches to gathering local norms at the classroom/building/district levels, sampling procedures, data collection, and options for establishing norms.

Best Practices in Developing Local Norms for Problem Solving in the Schools

Lisa Habedank
University of Oregon

OVERVIEW

A sample of student behavior in isolation is no more useful than a photograph of a stranger found on the street. Without a meaningful context, student performance may be momentarily interesting but will not have utility in solving educational problems. So, student performance is placed in a context, often the context of (a) the student's own past performance and (b) how that student compares to what is expected of all students. For example, if a school psychologist were told that Ricky read 50 words a minute in grade-level reading material, he or she would likely ask "How does that compare to his reading in the past?" and "What do other students in his grade read like?" or "How many words per minute would we like Ricky to be reading?" Normative comparisons are used to help answer the latter two questions, questions about what is expected of a student in relation to how other students perform on the same task.

A norm is a description of a population's performance on a set of tasks. It is usually made up of the performance of a sample of people selected to represent the whole population. For example, the norm sample may be designed to represent students across the whole nation (e.g., the national norm sample of the Woodcock Reading Mastery Test), students with a particular background or disability (e.g., the visually impaired norm sample on the Blind Learning Aptitude Test), or students from a specific educational system (e.g., the local norms of Wild Rice Elementary school on Curriculum-Based Measures of basic skills). Comparisons made using norms should always be phrased so it is clear which population the norm sample represents. In this chapter, the term *local norms* describes norms developed to represent students from a particular educational system. As such, they provide a comparison for where a student's performance stands locally — in the student's own education cooperative, district, building, or even classroom. Local norms would not provide information on how a student compared to a national standard and vice versa.

The use of norms in the schools is not a new phenomenon. Since the early 1900s normative comparisons have been used extensively in the schools to describe individual differences (Bergan, 1985). These comparisons, typically involving nationally normed, published achievement and intelligence tests, have been used widely as part of the special education screening and eligibility process. The concept of local norms, likewise, is not new. Many psychological measurement texts (e.g., Anastasi, 1988; Kubiszyn & Borich, 1990) describe local norms as norms developed by the test users themselves to represent a narrowly defined population. "These local norms are more appropriate than broad national norms for many testing purposes, such as the prediction of subsequent job performance or college achievement, the comparison of a child's relative achievement in different subjects, or the measurement of an individual's progress over time" (Anastasi, 1988, p. 97).

Many of the local norm references in the school psychology literature describe local norms developed on nationally normed, published tests in order to represent a specific region's population (Kamphaus & Lozano, 1984). For example, local norms created on the WISC in a school district with a large Mexican-American, Spanish-speaking population (Elliott & Bretzing, 1980) provide an alternative to the WISC's national norm comparison standard. Again, these local norms developed on nationally normed, published tests typically were used as part of the special education screening and eligibility process.

The use of local norms that more directly represent the goals and outcomes of general education, however, is a relatively recent phenomenon. For example, as part of a series of projects in the 1970s for the University of Minnesota's Institute for Research on Learning Disabilities, a normative database was developed for the Pine County Education Cooperative. The normative information was collected on basic-skills academic tasks normed on students sampled from several Pine County schools (Tindal, Germann, & Deno, 1983). Both the tasks normed and the way the data were conceptualized and used differed from past documentation of local norms in the school psychology literature.

The tasks — brief, standardized fluency measures in the areas of reading, math, spelling, and written expression — became known as Curriculum-Based Measures (CBM, Deno, 1985; 1986). The tasks represented "vital signs" of learning in important educational areas for all students in the education cooperative. The normative data collected on these tasks were used to describe the expectations for a student's basic skill performance in general education. Instead of taking a student in isolation and using normative comparisons to document a within-child discrepancy (e.g., a student's achievement-ability discrepancy) for eligibility purposes only, the Pine County norms were used in a way similar to peer referencing in behavioral observation. A behavioral observer uses a peer reference to define what is expected of the student in his or her environment and then uses that information for several purposes. For example, a target student's level of engagement could be compared to a peer's level of engagement to determine if a problem exists. The peer level of engagement could be used as the goal, and when the student's engagement once again fell within the range of the peer's, the problem would be solved. The Pine County CBM local norms provided a normative comparison, on relevant educational tasks, that could be used in this way. The performance of general education peers was compared to an individual student's performance to determine if a discrepancy between what was expected (the norm) and what occurred (the student's performance) existed (Deno, 1988). This same local norm could be used in goal setting and determining when problems were solved.

It is this application of local norms — selecting behaviors that are important in the general education environment, developing local norms that represent the range of performance in general education, and using norms and norm tasks as part of a problem-solving system — that will be the focus of this chapter.

BASIC CONSIDERATIONS

Strengths of Local Norms

Although developing norms does involve time and resources, the strengths of local norms can make this a wise investment. For most educational decision making, local norms are representative of a meaningful comparison group on tasks relevant to the problems at hand. Specifically, local norms may decrease the likelihood of bias in decision making and increase testing/teaching overlap and norm utility across educational decisions.

Decreasing the likelihood of bias in decision making. Test bias is a hotly contested political and legal issue in school psychology (Reynolds & Kaiser, 1990). Although much has been written about developing culture-free or culture-fair tests, bias can be conceptualized as a function of the decision-making process rather than an inherent quality of the tests themselves (Ysseldyke, 1979). Local norms can decrease the likelihood of bias in decision making because they represent a meaningful comparison group. Local norms represent how a student performs in relation to others from his or her grade and school, a comparison likely to be representative of the age, grade, race, educational background, geographic, and socioeconomic factors relevant for educating this student (Shinn, 1988). Gerber and Semmel (1984) argue that general education teachers already use their own "local norms," where a student's performance falls in relation to the other students in the class, to determine who gets referred for more intensive services. Local norms make this comparison part of systematic and data-based decision making.

Local norms also can decrease the likelihood of bias in decision making because they promote the identification of educational needs and a problem-solving orientation. When education professionals base decisions on agreed upon, important educational outcomes operationalized in the form of locally normed educational tasks, they can identify and help students who perform significantly below their peers and thus are at risk for failure in the schools and in society. Furthermore, local norms can be used to demonstrate whether the special instruction or intervention designed by the problem-solving team is working. Although having local norms will not guarantee a nonbiased assessment and decision-making process or effective programs for students, selecting students for special services based on reliable measurement of educational needs and then having an accountable system for addressing those needs is not likely to be considered biased and unfair.

Opportunity for greater teaching/testing overlap. One of the complaints about the use of nationally normed, published tests is the lack of teaching/testing overlap. In an analysis of the data from two research projects, Leinhardt (1983) concluded that the amount of overlap between the nationally normed tests and curriculum not only was minimal, but also was an important predictor of end-of-the-year test performance. Several other studies have documented that differing levels of test-content overlap with the curriculum affects student performance (Jenkins & Pany, 1978; Shapiro & Derr, 1987; Good & Salvia, 1988).

Local norms give the school system flexibility for developing comparison data on educational outcomes and tasks that students have been exposed to in the school curriculum. Instead of making decisions based on questions that may or may not reflect content taught as part of the school's curriculum — and often assessed using bubble sheets or requiring a small number of responses — schools can base decisions about students on tasks related to curricular content. This flexibility means that the norm comparison data is directly relevant for making decisions about a student's performance compared to local expectations.

Utility across educational decisions. Deno (1988) proposes that educating tough-to-teach students is a problem-solving process and "systematic efforts in problem solving require the organization and sequencing of activities — the use of a problem-solving model" (p. 12). He outlines five problem-solving steps, or decisions, that correspond to the administrative steps of most special programs. The five steps are (a) problem identification, (b) problem certification, (c) exploring solutions, (d) evaluating solutions, and (e) problem solution. Problem identification and certification correspond to referral/screening and eligibility/need decisions. Exploring solutions includes setting long- and short-term goals and establishing and implementing an instructional plan. Evaluating solutions involves monitoring student progress toward goals and making instructional changes when students are not making adequate progress. Problem solution corresponds to program exit decisions or movement to a less restrictive setting.

Normative comparisons typically are used in educational decision making only to identify and describe the severity of a problem (e.g., problem identification and certification decisions). Local norms can be used in these initial problem-solving steps to determine what is expected of the student. In addition, local norms tied to curricular goals and student outcomes are parsimonious with the information needed to set good educational goals, evaluate student programs, and make other important educational decisions for that student. For example, CBM data used in problem identification and problem certification provide the foundation for goal setting, progress monitoring, and further assessment for instructional planning. Throughout this process, comparisons to other students via local norms provide a context for decision making. Local norm utility across educational decisions will be discussed further in a later section of this chapter. (Two other chapters in this volume also describe the use of CBM local norms.)

A related strength of local norms is that all local educators can use the same general education outcomes "ruler" or decision-making framework for many types of educational programs such as Chapter I, English as a Second Language (ESL), Talented and Gifted (TAG), general education, and special education. Normative comparisons are already used to identify students for many types of educational programs. However, the tests used between and within these programs may differ, making it difficult to compare the achievement of one group of students (e.g., students served in Chapter I programs) to another (e.g., students identified as learning disabled with an Individualized Education Plan) and separating the decision making for special programs from general education expectations. Local norms can provide a consistent general education outcomes "ruler" that allows for a variety of comparisons between and within all of an educational system's programs.

Limitations of Local Norms

The limitations of local norms fall into three broad categories: (a) the potential for misinterpretation, (b) limitations on the use of local norms to define acceptable student performance and curricula, and (c) replicated effort.

Misinterpretation. Because not all educators are familiar with the use of local norms, it is important to define them. As with any type of educational assessment and normative comparison, parents, teachers, and others should be informed about who is represented in the normative sample and what the students were asked to do. It should be explained that the norm represents how students in this particular sample performed, what tasks were included, and how the scores were derived.

Using local norms with a small number of cases in the norm sample (e.g., fewer than 100 students per grade) can be problematic. If the sample size is small, the norm may be unstable and should not be used as the most important normative comparison for making eligibility decisions. Also, with a small sample size, infrequent elements in a population may not be represented. Small or limited sample size is not necessarily a problem, however, as long as the norm is interpreted appropriately. For example, if a classroom norm is used to help define what is expected of the student in that classroom, a statement should be made about the possibility that expectations of student performance in another classroom may differ. This does not mean the classroom comparison is not meaningful, however; it may be quite useful in understanding the difficulty a teacher is having in accommodating a student's needs.

Local norms and defining acceptable performance and curricula. Shinn (1988), in his description of developing Curriculum-Based Measurement (CBM) local norms for use in special education decision making, expressed concern that local normative performance would be seen as the goal for all students. "Another potential disadvantage exists when local normative performance is accepted as a goal for all children, which may suggest mediocrity" (Shinn, 1988, p. 76). Using a local norm to describe general education expectations does not mean that local normative performance is necessarily acceptable. For example, if a student's oral reading fluency is within the range of his third-grade peers — but his or her peers are reading a median of 20 words correctly per minute in typical grade-level material (1 word correct every 3 seconds) — the conclusion would be that the student is not different from peers. However, all the students are in trouble if they are expected to learn from that material. Regionally or nationally normed general achievement tests may be used periodically to assess the skills of the local school population and provide data about how the school population as a whole compares to regional or national standards.

A related concern is that developing local norms will somehow advocate the use of a particular published curriculum. Local norms tasks should reflect important educational outcomes. The norming materials themselves may or may not be derived directly from the school's adopted published curricula. Using local norm materials drawn from the published books and workbooks students use in the general education classroom is appealing because it makes the connection between general education expectations and the norming process more concrete. Right or wrong, success in these published materials is what the general education teacher sees in the classroom. "It is argued that regardless of quality of curriculum, it becomes *de facto* the decision-making standard for regular education. Students who fail to profit from the regular education curriculum, regardless of its quality, are viewed often as handicapped" (Shinn, 1988, p. 77). Having local norms drawn from published curricular materials does not mean that the adopted curriculum is the most effective, only that students are expected to learn from the adopted materials.

Replicated effort. Best practices in local norms development involves not only norming a task on the local population but taking a fresh look at the purpose and framework for assessment. By using local norms to define the expectations for students in the general education curricula, educational problems can be placed in a problem-solving context. Local norms used for problem identification and problem certification, however, will not provide a distinct advantage over national norms without a link between the locally normed tasks and (a) further assessment of the student's educational environment and performance and (b) goal setting and ongoing progress monitoring.

BEST PRACTICES

Selecting Important and Valid Behaviors to Norm

Prior to developing local norms, decisions must be made about the behaviors or educational tasks that will be normed. Examples of local norms in the recent school psychology literature and in this chapter have been associated with Curriculum-Based Measures (Marston & Magnusson, 1988; Shapiro & Derr, 1990; Shinn, 1988, 1989; Shinn, Nolet, & Knutson, 1990). Developing local norms using behaviors important in the general education environment could include other areas of assessment and norming tasks. For example, local norms could be developed on social behaviors, prereading tasks, physical education skills, or the use of basic skills or content tasks other than CBM tasks. What is most important in making decisions about what to norm is that the data are relevant and valid for decision making.

Choosing relevant areas of assessment. To be relevant, local norm data must be related to *important* educational outcomes for students. Developing local norms on spelling in first grade, for example, would be relevant in a school that had determined spelling skills were important in first grade and therefore were part of the first-grade curriculum. First grade spelling norms would not be relevant in a school that did not emphasize or teach spelling to first graders. This chapter has focused on norms that reflect general education expectations. Local norms in basic academic skill areas are a logical place to begin because these areas generally have been the most "important," well-defined, and accepted educational outcomes in our schools.

Norms of behaviors not tied to general education expectations will have limited utility across programs and educational decisions. For example, local norms could be developed on basic skills in languages other than English, even if those other languages are not part of the general education curriculum. Non-English norms provide a potentially useful comparison for decision making and goal setting for students in English as a Second Language (ESL) programs (Baker, 1992). However, Non-English norms would not be useful for any other group of students in the school, and there is a danger that the norms and norm tasks would promote a separate standard or decision-making process for ESL students. Assessment utilizing norms reflecting both general education students and tasks and a more limited group of students and tasks would be helpful in this situation. Using typical general-education student performance in English as one long-term goal, typical Spanish-speaking or ESL student performance in Spanish as another long-term goal and monitoring progress in both would be one example of combining the two.

Choosing valid measurement tasks. To be valid, local norm data must be reliable and accurate, have relatively normal distributions, and be sensitive to educational change. To increase the likelihood that a local norm has these qualities, tasks that are normed must have standardized administration and scoring procedures, with proven test-retest reliability and content validity. To be useful in decision making, the norms must reliably differentiate students' levels of skill on the task (e.g., performance on the tasks needs to be relatively normally distributed). The further a distribution is from being normal, the more difficult it becomes to use the norm to set goals or determine if a student being assessed is different from peers. The tasks being normed also must provide enough opportunities for responses to show an increase when that skill is taught in the classroom.

The use of Curriculum-Based Measurement tasks. It is a challenge to find measurement tasks that (a) fulfill the validity requirements, (b) are time-efficient and affordable, and (c) provide data tied to important general education expectations. This challenge is one reason that local norming in the basic skill areas developed in conjunction with CBM. CBM tasks have a database documenting their reliability, validity, sensitivity (Marston, 1989), and relatively normal distributions in local norm data collection (Tindal et al., 1983; Magnusson, 1986). Furthermore, CBM is not just a technology but a measurement system designed for use in a problem-solving system. Using local norms to operationalize the expectations of the general education environment is one of the defining characteristics of CBM (Deno, 1985; 1986). Because CBM tasks are so closely tied to the concept of developing and using local norms in a problem-solving system and have a database supporting their use, the examples in this chapter will be based on CBM data in the basic skills areas of reading, math, spelling, and written expression. However, the underlying concepts and steps of norm development could be applied to other behaviors that provide relevant and valid data for decision making.

STEPS IN DEVELOPING LOCAL NORMS

Once decisions have been made about what behaviors will be normed, a series of steps can be followed to develop the norms themselves (Ball, 1993). The steps are presented in Figure 1.

Select a Level of Norm

The three basic levels of local norms are classroom, school-building, and school-district norms. Classroom norms are developed by sampling students from an individual classroom and testing them. Building norms are developed by sampling students from each grade in a school building and testing them. School-district norms can be developed in two ways: (a) selecting a sample of students in each grade from the entire school district population or (b) developing norms in each building and then aggregating all the building norms. The former is generally less expensive, but aggregated district norms provide the benefit of having both building and district norms at your disposal. Each level of norm has its own characteristics.

Classroom, building, and district norm characteristics. Classroom norms are a great way to get started and provide the most direct measure of what is expected of a student in his or her own classroom. However, with such a small norm sample, estimates of the variability within the classroom are problematic and stable percentile ranks cannot be developed. Classroom norms can be used in the prereferral or IEP process to identify problems and prioritize student needs. They are useful for setting goals for a student or group of students. For example, the goal for low readers in a class could be to perform within the typical range on spring reading norms by the end of the year. Classroom norms also have been used in determining when a student may be transitioned to a less restrictive environment, for example, from a resource room setting to the general education classroom (Shinn, Habedank, Rodden-Nord, & Knutson, 1993).

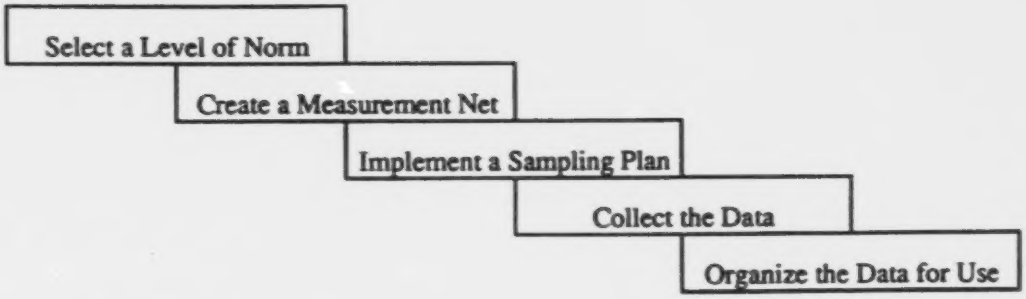
District norms, on the other hand, provide a more consistent estimate of the performance level and variability of the students within the district. The disadvantages of district norms are that they are a less precise measure of the least restrictive environment for a particular student (e.g., that student's classroom) and require relative homogeneity of curricular objectives across schools. District norms, like classroom norms, can be used to identify problems, set goals, and prioritize needs. If the district norm sample is 100 per grade or larger, the norms are stable enough to be used in problem certification decisions as well. Aggregated district norms also could be used to compare the performance of students in different schools for resource allocation and system-wide programmatic purposes.

Building norms' characteristics lie somewhere between classroom and district norms. They are a more precise estimate of the least restrictive environment than district norms and provide a more stable estimate of performance than classroom norms. Building norms can be used for the same general purpose as district norms, including problem certification if the student sample has at least 100 students per grade.

Factors in level of norm decisions. Important factors when selecting a level of norm are the (a) characteristics of the local population, (b) amount of curriculum chaos in the district, (c) political and economic structure of the area, (d) decisions for which the data will be used, and (e) economic and other resources available (Ball, 1993). As alluded to in the characteristics of different levels of norms, these five factors must be considered and balanced in order to determine which level of norm is both meaningful and feasible.

If the school district has relatively homogeneous school populations, district norms are appropriate. When the district is characterized by heterogeneous schools, such as schools that differ in terms of student's language, cultural, and/or socioeconomic backgrounds, district norms may not provide the most meaningful representation of student expectations. If

FIGURE 1. Steps in developing local norms.



the curricula (e.g., grade-level educational goals and scope and sequence of instruction) across a district are relatively consistent, then district norms are appropriate. However, if the curricula are very different, then district norm data would not be relevant to many building decisions and building norms may be more appropriate. Schools that have a different structure, get funded differently, or have a history of functioning independently from the district "norm" would warrant the development of building norms. If the funds or personnel are unavailable for district norming, building norms may be more feasible. If resources for building norms are unavailable, norms can be developed one classroom at a time.

Determining the level of norming will be dependent on the circumstances in the school district. Each school district will have differing resources and needs that will change over time as well. Once a group of people have some experience developing one level of norm, they can use the knowledge they have gained to develop other levels of norms.

Create a Measurement Net

The second step in developing local norms is creating a measurement net. A measurement net is a grid of the grade levels and representative materials used in norming. The materials should represent the domain of the school year curriculum for *typical* general education students. For example, if a local norms comparison is desired for mathematic computation at Wild Rice Elementary School, a measurement net could be developed that detailed the grade levels where a math norm comparison would be useful in decision making. At each of these grade levels, the mathematic operations and problem types that best represent student expectations at that grade can be determined and grade-level math probes developed. When completed, the measurement net provides a guide for the student stimulus materials that must be developed. A CBM local norm measurement net for the four basic skill areas is presented in Table 1.

Identifying typical material. It is important that the measurement net truly represent *typical* material in each area and grade, not end-of-the-year goals nor preskill mastery objectives. Not every skill or level of difficulty can be represented in the norm materials, but choosing materials that best represent typical skills and levels of difficulty will allow for meaningful norm data. Many people and resources may be used to operationally define "typical." District curriculum specialists, adopted curriculum scope and sequence charts, and teachers provide the resources for answering questions such as: "What material is most frequently used?" "What levels of material are most representative of each grade's goals and objectives?" and "What materials are the majority of the students placed in for most of the school year?" The actual norming materials can be drawn directly from the adopted published curricular materials identified as typical or can be *generic* materials created to reflect typical materials at each grade level. The Monitoring Basic Skills reading maze, spelling, and math materials (Fuchs, Hamlett, & Fuchs, 1990) and the Test of Reading Fluency passages (Deno, Deno, Marston, & Marston, 1987) are examples of generic materials that may coincide with typical materials in use in the schools.

Measurement net dos and don'ts. Some hints for creating a measurement net will help avoid problems later. Field test your materials. Avoid material that is too easy (no variance) or too difficult (nothing to measure). Keep in mind the decisions you want to make using local norms. For example, if you are not interested in using normative comparisons for decisions about kindergarten students, then do not include kindergarten in your measurement net. Measurement nets should differ according to differences in the curriculum and level of norming.

Implement a Sampling Plan

"The normative sample is important because it is the group of individuals with whom a tested person is compared. Norms should be representative of the

population to which comparisons are made" (Salvia & Ysseldyke, 1991, p. 118). One of the strengths of local norms is that the data represent a meaningful comparison population: the students in the same school, curricula, age, grade, geographical area, and the like as the student being compared. A local norm does not necessarily mean norming the entire population, however. It is usually much more efficient to sample from the local population. A sampling plan must be developed that balances the resources available, representativeness of the sample, and information desired.

For classroom norms, a minimum of 7 to 10 students is necessary. Three methods of sampling students for classroom norms have been used: (a) creating a random subset of 7 to 10 students chosen from the entire class, (b) creating a subset of 7 to 10 students randomly selected from a pool of "typical" students identified by the teacher, and (c) a combination of testing all the students in the class for group administered tasks and selecting a subset of 7 to 10 students for more time-consuming individually administered tasks (e.g., oral reading). Choosing every *n*th name in the list from an alphabetized roster of student names or having a computer-generated random selection of students are the most typical ways to obtain a random sample of students.

At the building level, 15% to 20% of the students at each grade level, with a minimum of 20 students per grade, should be randomly sampled (Tindal et al., 1983). If building-level percentile ranks are desired, a sample of 100 students per grade is needed. Aggregated district norms can be developed by combining building norms if standard measurement materials have been used. If district-only norms are developed, a random sample of 100 students per grade is needed (aggregating across years if necessary to get 100 students).

Collect the Data

Data collection begins once the foundation has been laid for collecting well-developed norms: the level of norms has been selected, the measurement net filled in, and a sampling plan has been used to identify which students will be tested. Successful data collection hinges on the development of student testing materials, training data collectors, and scheduling when and where data collection will take place.

Materials and training. Student materials need to be prepared that are clear and time-efficient, for example, in booklet form with a place to summarize the data on the cover. Data collectors must be recruited and trained. Getting people involved in the data collection can be a good way of making the data meaningful for them. Parent volunteers, teachers, aides, school psychologists, principals, and school board members can be data collectors. Training materials should be developed so that the training itself is clear and consistent, and the data collectors leave training reliable and efficient in performing the norming administration and scoring procedures. Standardized administration and scoring, clear scheduling and materials, and monitoring integrity of data collection through spot checks or checklists also are key aspects in the collection of reliable norms.

Scheduling. The dates and logistics for norming must be scheduled as far in advance as possible to avoid conflicts. To get a picture of student performance throughout the year, trimester norming (e.g., Fall, Winter, Spring) is recommended, using equivalent but not identical norming materials each time (Shinn, 1989). Of course, classroom norms can be collected almost spontaneously if a classroom comparison is relevant to a decision being made and the materials and trained personnel are available. Norming can take place either within individual classrooms or at a central location in the school(s) such as a cafeteria or media center.

Organize the Data for Use

Because there are many potential uses for local norms and different consumers of norming information (e.g., parents, teachers, administrators), the norm data need to be organized so that they are easily and accurately interpreted. The data can be summarized at four different levels: (a) individual student raw scores; (b) classroom ranges of scores, medians, and rank orderings; (c) building-level ranges of scores, medians, rank orderings, and perhaps percentile ranks; and (d) school-district-level ranges of scores, percentile ranks, descriptive statistics, within-grade frequency distributions, and across-grade comparisons. One rule of thumb is that pictures communicate more clearly than tables and lists of numbers, so graphs that accurately represent the data are highly desirable.

Tables and graphs. Examples of tabular and graphic displays of classroom norm data are presented in Table 2 and Figures 2 and 3. Similar tables and graphs could be used to organize building and district norms. Table 2 presents a rank order of the students by raw score and also gives the range and median. Students in general education only, Chapter I, and special education in reading are separated so that comparisons of the achievement levels of students in these programs can be made. Additional descriptive statistics such as group averages and standard deviations could be added to the table for building and district norms. These same data are then presented in the form of a histogram or bar chart (Figure 2), and a frequency polygon (Figure 3). The histogram reflects the rank order information in visual form. The frequency polygon makes the norm distribution visible.

Percentile ranks are useful when making problem identification, certification, goal setting, and problem-solution decisions. For example, the district may determine that all students who are at or below the *n*th percentile on local norms are in need of further assessment, and students at or below the *n*th percentile are eligible for a particular program. The actual percentile cut-offs used by the district would be determined by considering several factors such as program intent, resources, federal or state guidelines, historical data, and so forth. Percentile rank data may be organized on tables by listing the raw scores and corresponding percentiles for each grade and norm-

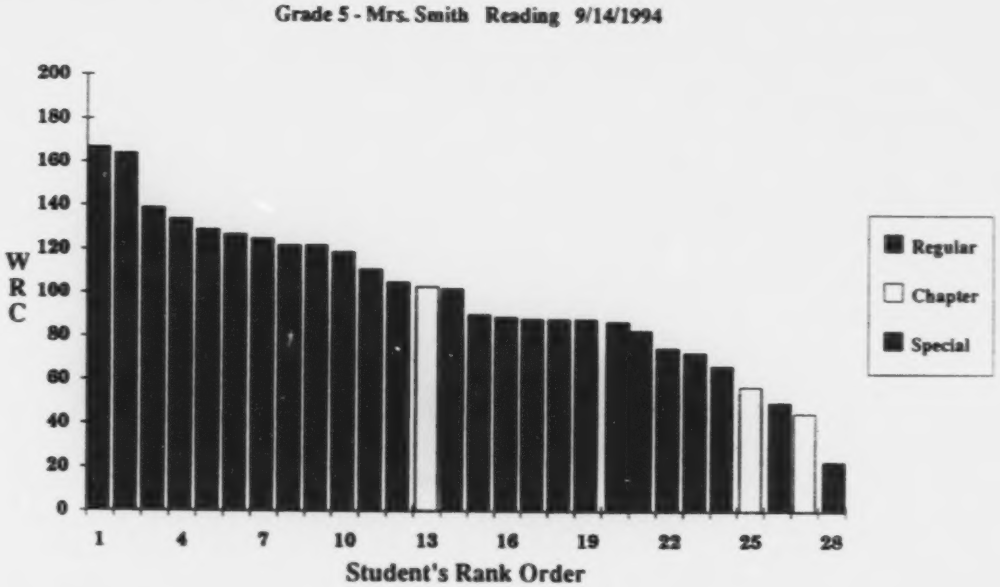
ing task. Percentiles also can be represented on "cut-off" charts that provide a visual display of where a child's performance falls in relation to the local norm (Gilbert & McKibben, 1993; Tindal & Marston, 1990). An example of a percentile rank cut-off chart is presented in Figure 4.

Also, percentile ranks could be used to determine which score corresponds to the Spring 50th percentile, and therefore what the goal would be for a student expected to be reading like an "average" student by the end of the year. A useful graphic for representing "typical performance" across grades is presented in Figure 5. The shaded bands represent performance between the 16th and 84th percentile at each grade level, with a line at the 50th percentile (Gilbert & McKibben, 1993). This same type of figure could be used to summarize typical performance within a grade across the three norming periods.

FIGURE 2. Sample classroom norm rank order histogram.



Computer programs. Many other types of graphs and tables could be used to organize and summarize the data; only a few of the possibilities have been provided. Regardless of the format chosen, however, having the normative data entered into a computer spreadsheet will make data presentation easier. Some type of computerized data organization and management usually is necessary for building and district norms, and desirable even for classroom norms data presentation. The programming and charting capabilities of spreadsheet programs such as Microsoft Excel (1993) have been used to organize and summarize local norms data. Zephyrus (Tilly, 1993) is a computer program designed specifically for local norming. Data entry and the creation of tables, histograms, and reports can be individualized to the behaviors and grade levels normed using the Zephyrus program.

Summary

The steps involved in developing local norms follow a logical sequence. Selecting a level of norm provides an opportunity for reviewing the purpose for developing the norm and the unique characteristics and needs of the local school(s). The completed measurement net is a blueprint for developing norming materials and forces the norm developers to closely examine the local curriculum content, instructional focus, and goals and expectations. The sampling plan identifies the students who will make up the norm sample and allows for further logistical planning such as scheduling and final materials preparation. The normative performance data is finally obtained by collecting and organizing it for use in educational decision making.

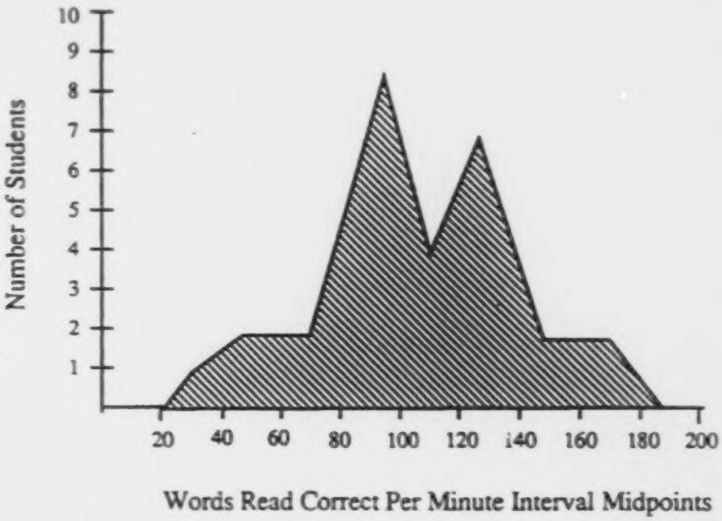
UTILIZING LOCAL NORMS IN A PROBLEM-SOLVING SCHOOL SYSTEM

One of the strengths of local norms is increased utility across educational decisions. What national norm comparisons often lack is (a) the ability to consider the student's immediate environment in defining problems and (b) a tie between the information used to define the problem and other decisions in the public school system. Local norms operationalize the expectations for a student's immediate educational surroundings and can be useful across the range of educational decisions, from problem identification to problem solution. A summary of local norm utility across decisions is presented in Table 3.

Problem Identification and Certification

Like national norms, local norms may assist in problem identification and certification decision making. A problem can be defined as the difference between what is expected and what occurs (Deno, 1988). Local norms can be used to define what is expected of a student. For example, comparing a student's score to a local oral reading norm can determine if the student's reading score falls within the average range of other student's in that district, building, or classroom. That average range represents what the teachers see as typical reading performance in the classroom. If the student's reading falls below that average range, educational personnel may con-

FIGURE 3. Sample classroom norm frequency polygon.



clude that the student's performance does not meet expectations and therefore a problem exists. In this case, more intensive assessment, and perhaps educational services, are warranted. If, upon further assessment, the student's reading scores continue to fall far below typical students' performance in the local norm, evidence that the problem is important and warrants intensive school services (e.g., special education) is supported. This further corroboration of the importance of the problem is part of a multifaceted assessment for making problem certification decisions about students.

Exploring and Evaluating Solutions

Local norms can be useful at several other levels of a school's problem-solving framework. Once the problem has been validated, goals are set and services are provided to meet the student's needs. These services must be evaluated for their effectiveness and modifications made if goals are not being met. Local norms can be used to help set goals. IEP and Chapter I goals, for example, can be based on the typical performance of students in the local norm sample. Tying student goals to typical general education performance maintains congruence between what the student is expected to accomplish and what performance is needed to fit into the general education setting. Local norms also can be used to clarify placement in, and organization of, the variety of special services available in the school. By obtaining a picture of the local student population's range of skills (the local norm) and knowing which sections of that population are served by the resources available (e.g., where students in Chapter I, ESL, special education, TAG, and at-risk programs perform on the norming tasks), decisions about services for individual students and the organization of programs can be more data based.

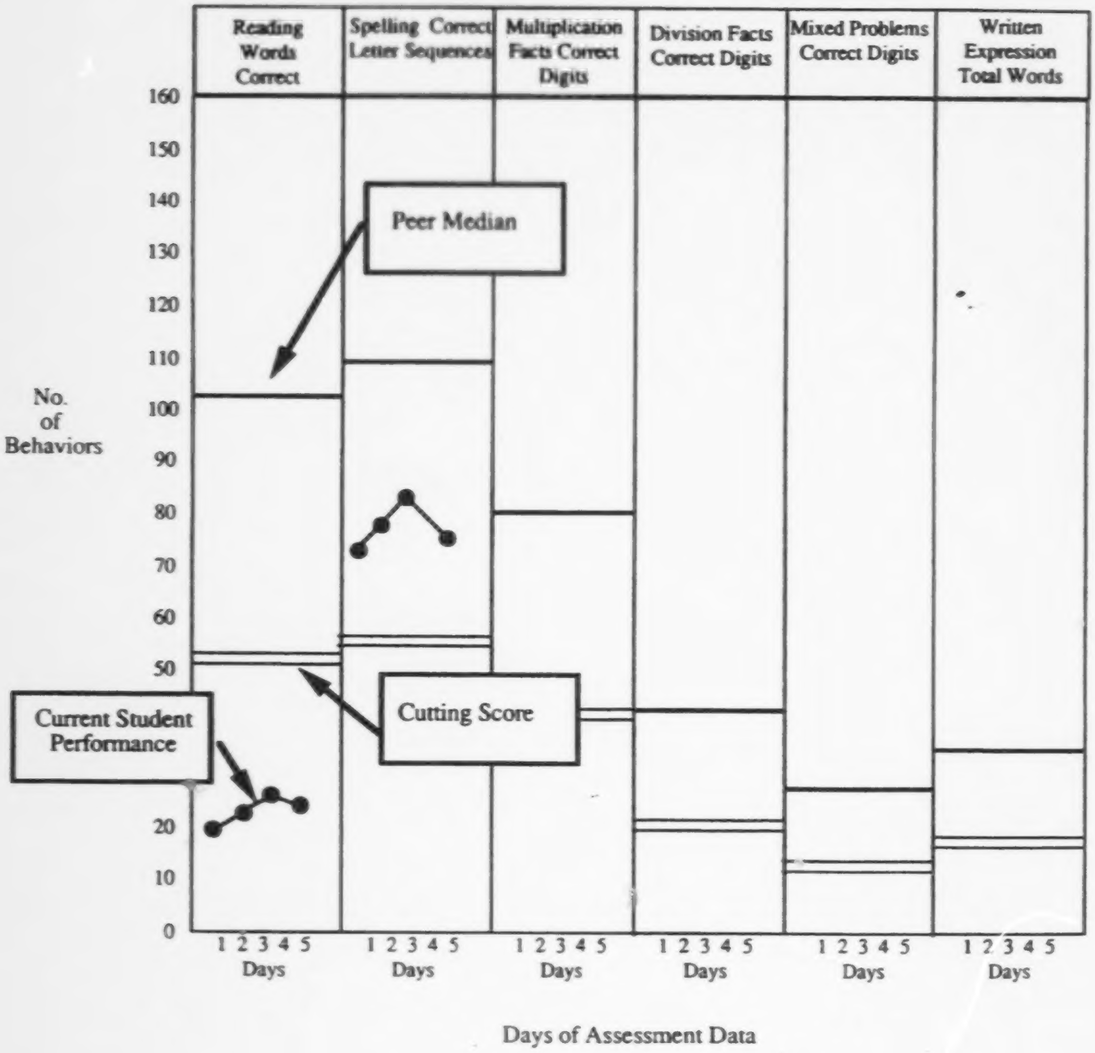
Problem Solution

Finally, local norms can be used in determining when a student can be exited from a program or moved to a less restrictive environment (i.e., problem solution or reintegration). Student performance within the range of typical students suggests consideration of exit from the special program. Relatedly, student performance within the range of the lowest achieving general education students in the classroom, school, or district sample could be used to determine when a student could be reintegrated into a less restrictive setting (Shinn et al., 1993).

Local Norms and Program Evaluation

Although not directly tied to decisions about individual students, local norms collected across years also can be used to evaluate program/curriculum effects, given fairly stable student population and demographics. Likewise, local norms collected across years could be used to evaluate the effects of population or demographic shifts, given fairly stable service delivery systems and program/curriculum. Local norms collected for the purpose of program evaluation or other administrative purposes may require a higher level of expertise and more standard set of tasks and measurement materials than local norms developed for student-centered decision making (Tindal, 1988; Tindal & Marston, 1990).

FIGURE 4. Sample district norm problem identification cut-off chart.

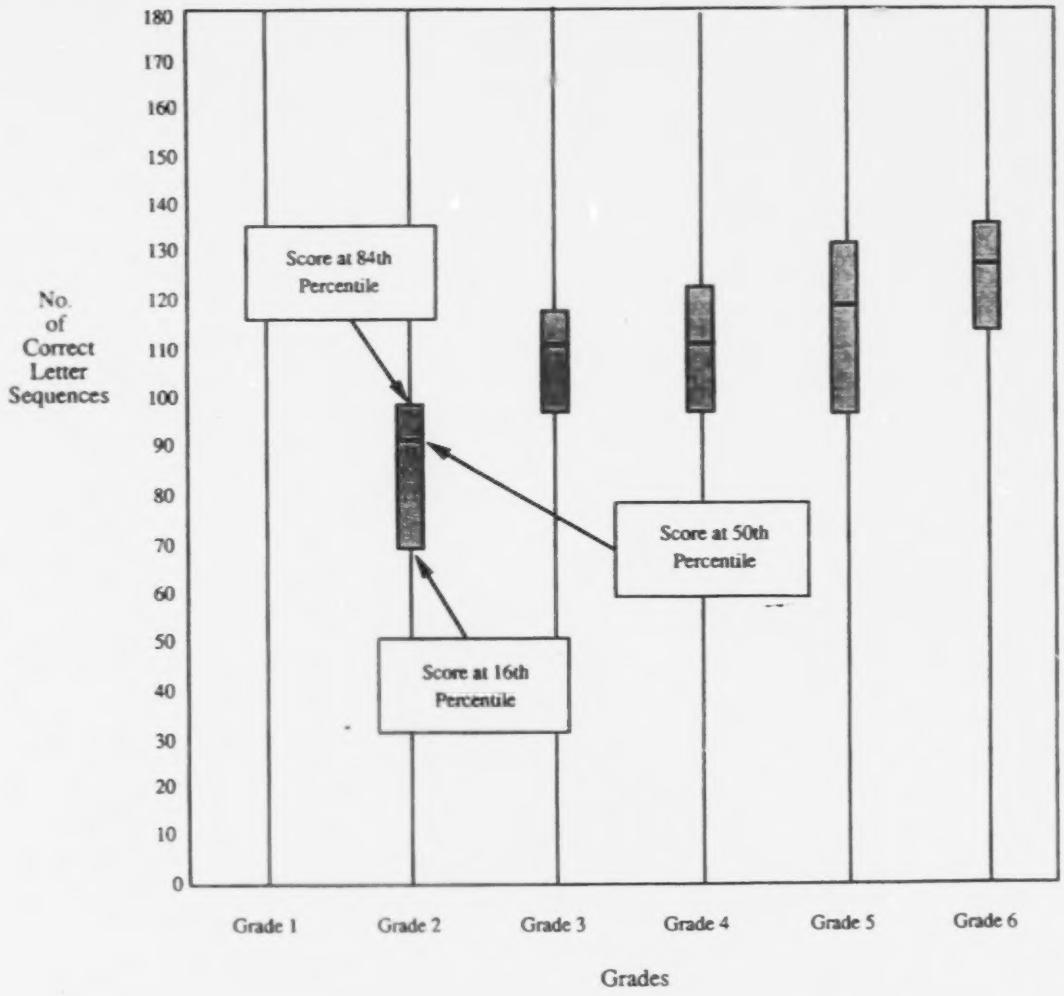


SUMMARY

Although the use of normative comparisons in the schools is common, developing and using local norms as part of a problem-solving system is still a relatively new area for school psychologists. A problem-solving system requires analysis of the educational context as well as the individual student. The context of the educational system — the class size, educational background, socioeconomic factors, student achievement levels, and so forth — will differ from district to district, school to school, and even classroom to classroom. For the school psychologist working with the staff and students in a particular system, local norms can provide a representative sample for local decision making and offer flexibility in which types of tasks are normed. These characteristics contribute to the strengths of local norms: decreased bias in decision making, increased teaching/testing overlap, and norm utility across educational decisions.

Developing local norms is a process of focusing on what information is most useful for educational problem solving and then implementing the five steps of norm development: (a) selecting a level of norm, (b) creating a measurement net, (c) implementing a sampling plan, (d) collecting data, and (e) organizing the data for use.

FIGURE 5. Sample district spelling norm across-grade distribution.



For maximizing norm utility in problem solving, best practices in local norm development would involve norming behaviors that are important in the general education environment and developing local norms that represent the range of performance in general education. By selecting important and valid behaviors tied to general education (e.g., Curriculum-Based Measures of reading, math, spelling, and written expression), the norm can be used to operationalize general education expectations. The process of problem solving then involves: (a) identifying a problem by examining if a particular student's performance or behavior is outside of the expectations of general education, (b) certifying a problem by showing whether the student's performance is so discrepant from peers that special services are warranted, (c) setting goals to get the student's performance back within the range of his or her general education peers, (d) monitoring student progress, and (e) determining when the student's performance is no longer outside of the general education expectations and the problem is solved. Throughout this problem-solving process, local norms provide a context for making educational decisions.

AUTHOR'S NOTES

This chapter was supported in part by Grant No. H029800051 awarded to the University of Oregon by the U.S. Department of Education, Special Programs Office. The views expressed within this chapter are not necessarily those of the USDE. The author wishes to thank Drs. Mark Shinn, Scott Baker, and Susan Green for their support in writing this chapter.

TABLE 3
Local Norms Utility Across Problem-Solving Decisions

Problem-Solving Decision	Use of Local Norms
Problem Identification (Screening)	Use local norms to determine if a performance discrepancy exists between a particular student and grade-level peers.
Problem Certification (Eligibility Determination)	Use local norms to decide if discrepancies are important enough that special services may be needed for problem resolution.
Exploring Solutions (Goal Setting and Intervention Planning)	Use local norms to facilitate goal setting. Select the level of skills required for success.
Evaluating Solutions (Progress Monitoring and Program Modification)	
Problem Solution (Exit from Programs)	Use local norms to decide if existing discrepancies are important or if alternative services are no longer warranted.

ANNOTATED BIBLIOGRAPHY

Shinn, M. R. (1988). Development of curriculum-based local norms for use in special education decision making. *School Psychology Review, 17*(1), 61–80.

This journal article describes the development and use of Curriculum-Based Measurement (CBM) local norms. Examples of applying CBM local norms in special education decision making are provided throughout. The use of CBM in decision making is presented as an opportunity to expand the role of the school psychologist. Technical adequacy and logistical issues in developing a local database are discussed.

Tindal, G. A., & Marston, D. B. (1990). *Classroom-based assessment: Evaluating instructional outcomes*. Columbus, OH: Merrill.

This basic assessment text addresses many of the issues involved in developing and using local norms. Tindal and Marston give guidelines for test reliability and validity that include sections on the size and comparability of the norm group (Chapter 6). The text provides a good overview of norm-referenced evaluation (Chapter 13), including examples of local norms. Different formats for local norm data display also are demonstrated.

Best Practices in the Assessment of Written Expression

Scott Baker
Dawn Hubbard
University of Oregon

OVERVIEW

As Connally (1983) notes "education is inextricably linked with the capacity to produce visible language" (p. xi). Functional literacy is a cultural imperative for all students (Deno, 1989), and although the development of reading skills has received the bulk of the literacy focus during the latest reform movement in education, the development of writing skills has also generated considerable attention. At least three reasons justify a chapter for school psychologists devoted to the assessment of written expression.

First, many students are not acquiring adequate written expression skills. According to the results of the latest National Assessment of Educational Progress (cited in Hooper et al., 1994), only 1% of fourth-grade students and 8% of eighth-grade students wrote a well-developed narrative, and only 22% of eighth-graders could develop an argumentative report. Writing problems surface early and in many cases remain with students throughout their educational experiences (Isaacson, 1985). In addition, written expression in the early grades is a good predictor of overall school success, and in many cases becomes the first indication of academic difficulty noticed by teachers (Isaacson, 1985). Along with reading, failure to acquire adequate skills in written expression constitute the greatest number of referrals to, and placements in, special and remedial education programs (Hallahan & Kauffman, 1986; Howell, Fox, & Morehead, 1993).

Second, writing instruction is beginning to play a more prominent role in general education classrooms. In many ways, effective written expression represents the culmination of formal educational experiences (Salvia & Ysseldyke, 1991). Writing is an extremely complex task and its development is significantly influenced by the kinds of opportunities students have in school to write (Hillocks, 1984). Teachers are moving away from instruction that focuses exclusively on the mechanics of writing to instruction that focuses on the range of tasks involved during the writing process (Raphael & Englert, 1990). To write well requires that students have an adequate knowledge base from which to draw content ideas, the skills to organize their ideas and present them in print according to established conventions, and sufficient self-monitoring strategies to guide the recursive writing process. School psychologists need assessment procedures that reflect the richness and complexity of the written expression process.

The third reason for a chapter on the assessment of written expression is that the very act of sequencing skills (i.e., gaining access to the relevant knowledge base, generating and sequencing ideas, and using strategies of self-monitoring to evaluate performance) is traditionally a source of difficulty for low-performing students, including students with disabilities (Englert & Raphael, 1989). If school psychologists are to play a prominent role in structuring general education environments so that more students develop effective writing skills, they will need assessment strategies that reflect the degree to which students are acquiring the range of skills being emphasized in classroom settings.

BASIC CONSIDERATIONS

The goal of this chapter is to provide a framework for assessing written expression, a framework adaptable to the diverse writing expectations and formats that characterize classroom settings. Two assumptions are made that serve to structure the assessment of written expression. First, assessment procedures should be guided by a decision-making purpose and the data collected should reflect that purpose (Deno, 1989; Salvia & Ysseldyke, 1991; Shinn & Hubbard, 1993; Shinn, Nolet, & Knutson, 1990). In this context, the purpose and relevance of assessment data should be clear to the readers, parents, and students who may be affected by the outcome.

The second assumption is that comprehensive assessment procedures should address not only student writing performance but also the environmental variables that may be contributing to writing problems or that can otherwise serve as intervention targets. Converging evidence in education and psychology indicates that student performance on academic tasks is the result of complex interdependent factors. The belief that student performance reflects strengths and weaknesses attributable exclusively to within-student factors is being replaced by models of achievement that stress the influence of student skills *and* environmental variables in achievement outcomes (Lentz & Shapiro, 1986). For that reason, environmental variables associated with the content of the classroom writing curriculum and the procedures the teacher uses to deliver the writing content are discussed in this chapter (Howell et al., 1993).

BEST PRACTICES

Assessing Written Expression within a Decision-Making Context

Best practices in the assessment of written expression should center on activities to make specific educational decisions. For example, decisions regarding individual students range from determining the validity of a student referral to evaluating the effectiveness of an intervention aimed at improving student writing performance. A decision-making model proposed by Deno (1989) is sufficiently both broad and comprehensive to allow school psychologists from a variety of theoretical orientations to conduct assessments of written expression within a common decision-making context. In Deno's (1989) data-based problem-solving model, five types of decisions are identified. These decisions are depicted in Table 1, along with the assessment variables associated with each decision and general strategies for data collection.

In assessing written expression, the type of data collected and the ways the data are used depends on the decision being made. Although there is clear continuity from one decision to the next, the model does not need to be used in a lock-step fashion. For example, data-based decisions about student progress can be undertaken without first determining that a student is eligible for special education services. The majority of school psychologists, however, need comprehensive assessment strategies they can use in a step-by-step sequence. For this reason, a brief description of each decision is presented in a way that highlights the sequential nature in which the model can be used.

Screening decisions. The primary purpose of a screening decision is to determine if a student's performance in written expression is of sufficient concern to warrant a comprehensive writing assessment. The primary assessment task at this stage is to compare the target student's performance with typical peers from the same class, grade, or district. In addition, it is important to clarify the teacher's primary areas of concerns and to determine if instructional attempts to address the problems have been attempted. As with any assessment, more than one source of data should be collected to make a decision involving an individual student (Salvia & Ysseldyke, 1991). This is especially true in written expression because writing measures tend to be supported by lower reliability and validity data than other basic skill areas (Marston, 1989). Thus, a screening decision might be based on a direct measure of writing performance as well as student performance on a group-administered published test.

Program-eligibility decisions. The primary goal in making an eligibility decision is to determine if the resources in general education are sufficient to meet the instructional needs of the student or if additional resources, such as special education, are required. Achieving this goal requires a comprehensive assessment involving the collection of additional data on the student's writing performance as well as assessing the environmental variables that might be manipulated to improve student performance. Before anyone collects additional measures of student writing, a student interview should be conducted to determine if the student understands what the teacher expects in writing and has the knowledge preskills necessary to accomplish the writing objectives. For example, if some students are working on writing stories, do they understand the various elements that go into making a story?

An individual student's writing performance is assessed using multiple direct measures of writing. In addition, because of the importance of an eligibility decision, a published, individually administered measure of writing achievement should be administered to support the severity of the writing problem. The first step in assessing the writing environment involves conducting a teacher interview to confirm (a) the teacher's specific concerns regarding the target student's writing performance and (b) the content of the writing curriculum the teacher expects students to learn. The second step is to conduct classroom observations to determine the procedures the teacher uses to teach students the writing content and to observe the student's behavior during instruction.

Instructional-planning decisions. When the target student is found eligible for special education services, the purposes of instructional planning decisions are to determine (a) appropriate goals and objectives for improving student writing performance, (b) the procedures that will be used to monitor writing progress, and (c) the curriculum content and instructional delivery procedures that will be used to help the student meet his or her writing goals and objectives (Fuchs & Shinn, 1989). Additional assessment data do not have to be collected during this stage. The data collected to determine if the student

* Optional

was eligible for special services should be sufficient to plan the student's writing program and establish a progress-monitoring system.

Progress-monitoring and intervention-implementation decisions. The primary purpose in monitoring student progress is to determine the adequacy of student growth toward the specific writing goals and objectives identified in the instructional planning stage. The more frequently student progress data are collected, the sooner changes can be made in writing programs leading to insufficient rates of progress. Thus, measures of student progress should be sensitive to small changes in student performance and capable of frequent administration. When student progress is not adequate, the intervention should be evaluated and changes made in environmental variables in an attempt to increase the rate of student progress. Evaluating the implementation of the intervention typically involves an interview with the student's teacher to review the intervention and discuss changes that might facilitate student progress. Additional classroom observations can provide a more accurate assessment of how the writing program is being delivered and possible environmental variables that might be manipulated to enhance student progress.

Program-evaluation decisions. The two primary purposes of making program evaluation decisions are to summarize the overall effectiveness of the writing program at two levels and to determine if the student's writing performance continues to require services beyond general education. The first level of evaluating the effectiveness of the writing program is to summarize student progress toward individually referenced goals and objectives. At a second level, direct measures of a student's writing performance are compared to peers from the same class, grade, or district to determine how the severity of the student's writing discrepancy from peers has changed over time. The student's teacher also should be interviewed to determine the degree to which the writing program was implemented as planned and discuss changes the teacher would like to see in the student's writing program. Classroom observations also can be conducted to evaluate how additional environmental variables may be facilitating or inhibiting a student's writing progress. The combination of the two levels of summarizing student writing performances and the analyses of environmental variables are used by a multidisciplinary team to determine if services beyond general education are still needed for the student to make adequate writing progress (Allen, 1989).

Assessing Environmental Variables

Assessing variables in the writing environment is important to determine if a student is eligible for services beyond general education, to identify potential intervention targets in planning instruction, and to evaluate the extent to which interventions have been implemented as planned. An interview with the student's teacher is the best way of gathering data about the content of the writing curriculum and the methods the teacher plans to use to teach writing. Classroom observations are necessary to assess the instructional delivery procedures the teacher actually uses to teach writing, as well as to gather information about the student's behavior during instruction.

The instructional planning form. Writing instruction varies considerably from classroom to classroom (Hillocks, 1984). An instructional planning form (IPF) is used to gather information from teachers regarding the content and delivery of writing instruction. The interview format of the IPF involves a framework for identifying possible intervention targets when student progress is not adequate. The completed IPF in Table 2 details what might be a writing program for a student in the third grade. The five major headings (i.e., Instructional Procedures, Materials, Arrangements, Time, and Motivational Strategies) address variables in writing instruction that can be manipulated to increase student writing performance. For example, one possibility for increasing the student's writing fluency referred to in Table 2 might be to increase the amount of time the student spends in journal writing from 10 to 20 minutes per day.

The IPF should be completed by having teachers "talk through" their typical classroom writing routines. Discerning the primary writing skill and the strategies the teacher uses to teach the skill is the most difficult component to fill out on the IPF. Because there are many ways to describe a particular focus or skill, it is important to clarify with teachers what their description of activities in those two categories mean. A completed IPF serves as a description of the initial writing program to help a student meet specific writing goals and objectives. When student progress is inadequate, the school psychologist and teacher should use the IPF to identify where and how changes might be made to increase student growth. Classroom observation procedures are used to document the extent to which the components on the IPF are implemented and to supply additional information concerning possible interventions that might be successful in increasing student performance. Although it cannot be predicted in advance that a particular writing program will succeed with a given student, regardless of how well the program is planned and implemented (Deno, 1990), research evidence suggests that certain types of classroom writing environments have a higher probability of improving writing proficiency than others.

Traditional classroom writing environments. Traditional classroom writing environments frequently focus on student adherence to writing conventions such as spelling, punctuation, grammar, and handwriting (Englert & Mariage, 1992). On the IPF, these would be identified under *Focus or Skill*. In the early elementary grades, for example, the focus tends to be on punctuation skills. Students frequently practice punctuation skills by filling in blanks on worksheets (Bridge & Hiebert, 1985). Occasionally, there is verbatim copying of letters and sentences. During later elementary grades, more attention is directed to copying activities designed to improve punctuation skills and develop proficiency in identifying parts of speech (Bridge & Hiebert, 1985). At the secondary level, the focus tends to be primarily on the completion of grammar exercises (Applebee, 1981). On the IPF in Table 2, 15 minutes per day is allocated to grammar and conventions. More time is allocated to this activity than any other, which is an accurate reflection of what occurs in typical classrooms (Isaacson, 1987).

School psychologists should be aware of at least three problems associated with traditional classroom

TABLE 2
Instructional Planning Form for a Student in Grade 3

Instructional Procedures: *Focus or Skill*	Instructional Procedures: *Teaching Strategy*	Materials	Arrangements	Time	Motivational Strategies
Writing fluency	Student directed	Student journals	Independent	10 min. daily	• Praise • Student-selected topic
Grammar and Conventions	Teacher-led Instruction	Houghton-Mifflin Curriculum	Small Group (11:1)	15 min. daily	• Praise • Feedback • Group and individual points
Writing Process/ Narrative Text Structure	Teacher-led Instruction	• Overheads • Workbooks • Notebooks	Whole group (22:1)	20 min. M/W	• Praise • Feedback • Group and individual points
Writing Process	• Computer Program • Peer Editing	• Writing to Write Programs • Student writings	• Individualized at computer • Pairs of writers	20 min. T/Th	• Praise • Feedback • Group and individual points
Oral presentation of written products	Author's Chair	Student's written product	Whole group	20 min. Friday	• Peer praise • Feedback • Group and individual points

writing environments (Englert & Mariage, 1991; Isaacson, 1987). First, many traditional classroom environments allocate insufficient opportunities for students to engage in meaningful writing activities (Englert & Mariage, 1992). Research indicates that focusing on writing conventions does not result in overall improvements in students' written compositions (Hillocks, 1984). Second, many teachers rely heavily on published writing curricula to teach writing. Published writing curricula focus heavily on conventions, especially grammar, and studies conducted during the past 50 years clearly indicate that a predominant focus on grammar does not result in improvements in the overall quality of student writing (Hillocks, 1984). Third, traditional writing environments place nearly complete emphasis on product variables. Minimal attention is devoted to the critical skills needed for the development of overall writing proficiency (Isaacson, 1987). According to Isaacson (1987), writing environments should take into account *process* variables, such as selecting, combining, arranging, and developing ideas, as well as *product* variables, such as sentences and paragraph construction.

Changes in classroom writing environments. Recent changes in classroom writing environments offer numerous possibilities for facilitating instructional planning decisions in written expression. Many of these changes were fueled by Hillocks' (1984) meta-analysis of 60 experimental studies on written expression. Hillocks (1984) found that effective writing instruction was characterized by clear and specific writing objectives and activities in which students could interact with each other on writing tasks, such as small-group discussions focusing on the components of text structure. Hillocks (1984) also found that the most effective writing instruction consistently provided students with specific background information about a selected topic. Planned activities then were used to help students organize that information for the purpose of writing about the topic. Less effective environments included more traditional activities in which students practiced combining simple sentences into more complex sentences or applied evaluative criteria to a writing sample. Even less effective were methods in which students wrote about whatever interested them or analyzed features of exemplary writing samples to recognize and imitate those features in their own writing. The instructional approaches that resulted in the poorest writing performance were those that focused on studying parts of speech and sentences. Important changes in classroom writing environments influenced by Hillocks' (1984) findings include addressing the importance of text structure and making explicit the stages of the writing process.

Text structure. Awareness that written text involves recurring structures and patterns is an important prerequisite to mastering the writing process (Englert & Mariage, 1992). In many classrooms, students will be expected to develop writing skills to match different types of text structure. School psychologists should be familiar with the components of different text structures as they assess environmental variables that may be affecting student performance. For example, students may be expected to write proficiently using narrative text structure and many types of expository text structures such as compare/contrast, description, explanation, and persuasion (Englert & Mariage, 1992).

Narrative text structure is one of the earliest forms of communication acquired by children and contains a number of standard components (Englert & Mariage, 1992). Typical story grammar elements in narrative text include setting events, episodes, and conclusions. In some classrooms, teachers may expect students to include story grammar elements in their writing without providing explicit instruction on how that is done. In other classrooms, explicit instruction may occur on as many as eight or more elements (Simmons et al, in press).

Many students become implicitly aware of story grammar elements before they begin school, primarily through story reading at home. Even at the high school level, however, many low achieving students do not have a basic understanding of story grammar elements and, not surprisingly, the writing these students produce tends to be extremely poor compared to their classroom peers (Graves, Montague, & Wong, 1990; Meyer, Brandt, & Bluth, 1980). Recent developments in integrated curricula highlight one way to teach text structure elements in the context of written expression that may be useful in planning instructional programs (Langer & Applebee, 1987). For example, in an integrated reading and writing curriculum, students might learn about story grammar elements during reading instruction and then integrate those elements into their own written compositions (Raphael & Englert, 1990).

A study by Graham and Harris (1989) includes a number of components for planning instructional programs to meet the needs of students with poor writing skills. Graham and Harris (1989) taught students a question-asking strategy to improve their narrative writing. Their program began with prewriting activities that focused on identifying and generating story grammar elements using a mnemonic for seven story grammar questions. After students were able to recite the mnemonic and discuss its meaning, they generated story grammar elements while looking at a picture (Graham & Harris, 1989). A five-step learning strategy was used to help students write stories using the picture prompt. The teacher first demonstrated the strategy by using a "think aloud" technique. Students then practiced the five-step learning strategy as they wrote their own stories independently. To provide feedback, the stories were read by the teacher and students as a group, and if any of the story elements were missing, the group discussed how and where they could be added. The stories were returned to their authors for revision based on teacher and student recommendations.

The writing process. In general, environments that address the writing process attempt to make explicit the different stages of written expression, which can be used across different types of text structure. These stages include (a) establishing a purpose for writing, (b) generating and organizing ideas about what to write, (c) translating writing ideas into print according to established conventions, and (d) revising and editing drafts of the written product to match the writer's ultimate intent (Isaacson, 1985). Research evidence indicates that students make better writing gains when each of these stages is taught explicitly (Howell, Fox, & Morehead, 1993). In assessing the writing environment, school psychologists should document on the IPF and through direct observations the extent that explicit instruction is provided for each stage of the writing process. In many classrooms, the focus will be primarily on the third stage, that is, generating a writing product that adheres to established conventions. Little instructional attention typically is directed toward how to generate and organize ideas for writing nor on how to improve a written product through revision. Providing explicit instruction in the stages of the writing process should be considered a potentially valuable intervention when planning instructional programs for students.

Englert and her colleagues (Englert & Mariage, 1992; Englert & Raphael, 1989) have documented the effectiveness of explicitly teaching the stages of the writing process. For example, Englert and Mariage (1992) taught students a mnemonic strategy to help them learn to plan, organize, write, edit, and revise (POWER) their written products. After ensuring that students had learned the basics of text structure, they taught students the stages of the writing process through a sequence of explicit instructional activities. First, teachers modeled each stage of the writing process by "thinking aloud." For example, in modeling planning, teachers used self-talk and other overt procedures to clearly identify their audience and the purpose for writing. Then, to activate background knowledge teachers modeled brainstorming strategies to generate writing ideas, and ways to organize those ideas for content inclusion during the transcribing stage. After teachers modeled each stage of the writing process, they worked with students to write a class paper using the POWER strategy. Over time, students assumed more and more control of the writing process. Eventually they were required to complete writing projects independently, while continuing to demonstrate mastery of each stage of the writing process.

In summary, assessing environmental variables is conducted primarily to facilitate decisions regarding instructional planning. Typically, the data used to determine student eligibility for services beyond general education can be used to facilitate instructional planning decisions. However, it is not necessary to make an eligibility decision before gathering assessment data useful in planning instructional programs. The effectiveness of any program or intervention should be based primarily on student performance data. There are a number of ways to assess student writing. The methods vary in how students are asked to respond and the implications the data have for decision making.

Assessing Student Performance Variables

Direct and indirect measures can be used to assess student writing. Direct assessment measures (e.g., holistic judgments, objective indices, analytic ratings) are actual samples of student writing and provide for a rich analysis of student skills. In contrast, indirect measures are characterized by selection-type or contrived-response formats (e.g., multiple choice, matching, fill in the blank). Scoring indirect measures often involves determining if a response is correct or incorrect, and little information is obtained regarding how a student arrived at a particular answer. Although many indirect measures tap skills similar to those tracked by direct measures (Breland & Gaynor, 1979), the data typically are not useful beyond screening and eligibility decisions. A comprehensive review of indirect measures of written expression is provided by Bradley-Johnson and Lesiak (1989).

The remainder of this chapter will focus on the way direct assessment measures of student writing can be used to enhance decision making. All the procedures described can be used as part of a comprehensive assessment. Because there are few technically sound measures of written expression available, best practices in the assessment of written expression involves converging evidence among multiple measures of student performance (e.g., support from direct and indirect measures). This is particularly important when making eligibility decisions. Many of the procedures described next are best used for identifying student strengths and needs to plan instructional programs and monitor student progress toward short-term objectives.

Depending on the decision being made, student writing samples can be collected using standardized (e.g., curriculum-based measures, published norm-referenced tests) or nonstandardized procedures (e.g., portfolio samples, writing projects). When peer-referenced assessment data are needed for screening, eligibility, or program evaluation decisions, standardized procedures should be used. The writing samples generated to facilitate screening and eligibility decisions also can be used to facilitate instructional-planning and progress-monitoring decisions, but they may need to be supplemented with additional writing samples to obtain an accurate indication of student writing performance. Once the data are collected, assessment procedures are used to judge the student's overall writing proficiency and to identify skills in need of remediation.

Six components of written expression distinguish skilled from unskilled writers and provide an organizer for a comprehensive assessment of student writing skills. These six components are: (a) fluency, (b) grammar, (c) conventions, (d) content, (e) penmanship, and (f) student knowledge of the writing process (Graham, 1982; Isaacson, 1985). Students may have difficulty in one or more of these areas and assessment procedures should reflect the classroom teacher's concerns regarding student writing problems, as well as actual student performance on writing tasks. Techniques for assessing each component will be presented with a brief description of the scoring procedure and its primary application in decision making.

Writing fluency. Fluent writing is the ability to generate words, simple sentences, and compositions of gradually increasing length. Overall, the compositions of students with mild disabilities contain fewer words and shorter sentences than the compositions of students in general education (Myklebust, 1973; Nodine, Barenbaum, & Newcomer, 1985; Deno, Mirkin, & Marston, 1980). Fluency can be assessed by determining the number of words written in a specified time period or the average length of the sentences written. Fluency techniques can be illustrated using the writing sample provided in Figure 1.

Total words written. The number of words students write in 3 minutes in response to a story starter has been found to be a reliable and valid indicator of student writing proficiency (see Marston, 1989, for a summary of technical adequacy evidence). This measure of fluency has been examined in research on curriculum-based measurement (CBM) conducted during the past 13 years (Shinn, 1989). Writing fluency can be used to facilitate screening and eligibility decisions, student progress toward long-term goals, and program evaluation decisions.

Average sentence length. Average sentence length provides a general indication of variety and uniformity of sentences written. Average sentence length is calculated by totaling the number of words in the writing sample and then dividing that sum by

FIGURE 1. Katie's writing sample assessed using techniques related to fluency.

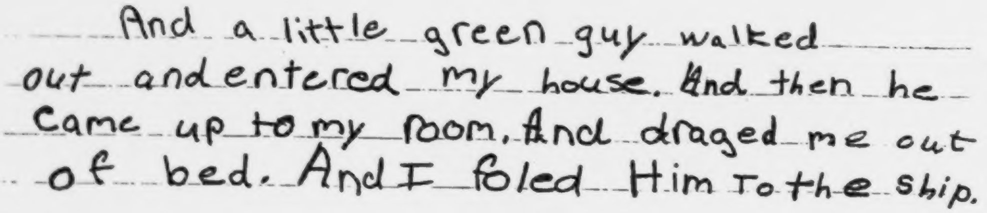
This morning a spaceship landed on the playground and …



And a little green guy walked
out andentered my house. And then he
Came up to my room. And draged me out
of bed. And I foled Him To the ship.

Fluency

Total Words Written = 32

Average Sentence Length (total words written ÷ # of sentences) = 32/4 = 8 words per sentence

the number of sentences in the sample. Cartwright (1969) suggests that mature writing is characterized by longer sentences (i.e., as students become more skilled in writing, their sentences become longer and more complex). Average sentence length can be used primarily to monitor progress toward short-term objectives.

Grammar. Poor grammar is the most frequent complaint about students' writing (Larsen, 1987). Appropriate grammar includes the correct use of words and combinations of words within sentences. Grammar can be assessed by examining vocabulary and sentence structure. All the techniques described are useful primarily for planning instructional programs and monitoring progress toward short-term objectives. Bonnie's writing sample in Figure 2 is used to demonstrate techniques to assess grammar.

Vocabulary. Selection of vocabulary to express meaning and communicate knowledge is critical to good writing. Research suggests that students with mild disabilities tend to use less "rich" vocabulary when they write than students without disabilities (Deno et al., 1980; Morris & Crump, 1982). Two ways to assess vocabulary include determining the variety and maturity of words used in a writing sample.

A type/token ratio can be used to examine the variety of words used in a writing sample. A higher type-token ratio indicates that the student is using a variety of words, with few words used repeatedly. The ratio is calculated by dividing the number of different words by the total number of words contained in a writing sample. If the student's ratio is compared to other students, or to previous samples of his or her own writing, the length of the writing sample should be the same for each comparison. For example, Cartwright (1969) recommended that the first 50 or 100 words from each writing sample be used. Use of mature words typically refers to words that contain seven or more letters (Howell et al., 1993). The proportion of large words is calculated by dividing the number of words containing seven or more letters by the total number of words.

Sentence structure. Numerous techniques can be used to examine the appropriateness of the words contained within a sentence. Two of the most common are sentence variety and syntactic maturity. Sentence variety refers to the types of sentences produced by the student, including sentences that are incomplete, simple, compound, complex, run-on, and fragmented (Cartwright, 1969; Howell et al., 1993). Tallying the types of sentences contained in a sample and summarizing the data in terms of percentages allows for comparisons across samples of varying length. As a student's writing matures, an increase in the percentage of compound and complex sentences should occur, along with a corresponding decrease in the number of simple, run-on, and fragmented sentences.

Syntactic maturity (i.e., the appropriate use of syntax and grammar) is most commonly measured by T-units (Hunt, 1965). A T-unit is described as "the minimal group of words that stands on its own as a sentence, with nothing left over" (Isaacson, 1985, P. 411). Compared to peers in general education, students with mild disabilities have been found to demonstrate difficulty with syntactical competence (Myklebust, 1973). For example, syntactical errors account for a large percentage of the expository writing errors made by students with learning disabilities (Thomas, Englert, & Gregg, 1987). To calculate syntactic maturity, average T-units are derived by dividing the number of T-units by the total number of words. To facilitate interpretation, T-units should be described in the

I saw what happened. They
told me to stay calm, they
will be right there They took
Nadine to the hospital and I
went with them. Nadine
got well soon After that we went
to the mall and bought some
clothes and we found our boyfriends!

GRAMMAR

Vocabulary

Type/Token Ratio (# of different words ÷ total # of words) = 54/73 = .7

Proportion of Large Words (# of words 7 letters or longer ÷ total # of words) = 6/73 = .08

Sentence Structure

T-Units = 11

Mean T-Units (total # of words ÷ total T-units) = 73/11 = 7

Sentence Type	Count
Incomplete	2
Simple	1
Compound	2
Complex	1

Paragraph Structure Checklist

1. Are the paragraphs properly indented?	No
2. Does each paragraph deal with a single topic?	Yes
3. Is a topical sentence used?	Yes
4. Are all the sentences related to the topic?	Yes
5. Are the sentences presented in a logical order?	Yes
6. Does the paragraph end with a logical conclusion?	Yes

FIGURE 3. Vance's writing sample assessed using techniques related to conventions.

Vance, Grade 3

Yesterday a monkey climbed through the window at school and …

Correct Writing Sequences = 10**

*Words spelled incorrectly are circled.

**Correct Writing Sequences are marked with a carat.

context of the types of sentences produced in the writing sample.

Related to examining the appropriateness of words within sentences is examining the appropriateness of sentences within a paragraph. Bradley-Johnson and Lesiak (1989) recommend assessing a paragraph structure by attending to (a) the use of topical sentences, (b) the relation between sentences to topic, (c) the logical order of both sentences within a paragraph and paragraphs within an essay, and (d) adequacy of transitional sentences.

Conventions. Many students with mild disabilities have difficulty attending to writing conventions, especially in the areas of spelling, capitalization, and punctuation (MacArthur & Graham, 1987; Thomas et al., 1987). Significant differences have been demonstrated between students with mild disabilities and general education peers in the number of words spelled correctly and correct writing sequences within a writing sample (Deno, Marston, & Mirkin, 1982; Tindal & Parker, 1991). Further, mechanical errors (e.g., punctuation and capitalization) are shown to interfere with the quality and quantity of student writing (MacArthur & Graham, 1987) and strongly influence teacher ratings (Moran, 1982). Techniques to assess the adequacy of writing conventions include determining the (a) number of words spelled correctly, (b) proportion of errors by category, and (c) number of correct writing sequences. Vance's writing sample in Figure 3 illustrates these three techniques.

Words spelled correctly. CBM procedures use the number of words spelled correctly as an index of student writing proficiency (Marston, 1989). A word is counted as spelled correctly if it can stand alone as a word in the English language. This measure may be used to facilitate screening and eligibility decisions, plan instructional programs, monitor student progress toward long-term goals, and evaluate the effectiveness of writing programs.

Proportion of errors per category. With writing samples that contain excessive mechanical errors, Howell et al. (1993) provide a summary form that includes over 50 capitalization and punctuation conventions. Errors are tallied and transformed into a percentage of errors per 100 words. Categorizing student errors may be useful to plan instructional programs and write short-term objectives.

Correct writing sequence. Determining the number of correct writing sequences is a CBM procedure designed to provide a general quantitative index of writing that considers grammar, fluency, and conventions (Videen, Deno, & Marston, 1982). A Correct Writing Sequence is earned for each pair of adjacent writing units (i.e., words and punctuation marks) that fits the context of what is written. This index may be used to assist with making screening and eligibility decisions, writing long-term goals, monitoring student progress, and evaluating the effectiveness of writing programs.

Content. Increased emphasis is being placed on improving the content of student writing. Students with mild disabilities tend to experience particular difficulty in (a) gathering original, related responses (Nodine et al., 1985), (b) including the basic elements of a minimal story (Nodine et al., 1985), (c) conforming to the topic and including elements of text structure (Englert & Thomas, 1987), and (d) using organizational strategies (Englert, Raphael, Fear, & Anderson, 1988). The content of written expression can be assessed using an analytic rating scale and ascertaining the degree to which specific text structure components are present in a writing sample.

Analytic rating. Several analytic rating scales exist for assessing the content of student writing. Generally, analytic scales provide an index of writing content by comparing a student's writing to other writing samples that have been rated according to a particular content dimension. For example, the dimensions included in a scale by Tindal and Hasbrouck (1991) are story-idea, organization-cohesion, and conventions-mechanics. Each dimension uses a five-point rating scale, with definitions for each point on each dimension used to judge the sample papers. Information from analytic rating scales may be useful for supplementing screening decisions and planning instructional programs.

Text structure components. The degree to which students include important writing components can be evaluated for different text structures. The specific components and text structures depend on the classroom instructional focus and content described earlier. Based on the teacher interview, assessment of text structure components can be accomplished by developing a checklist of the critical elements and rating or judging the student's demonstration of each element in the writing sample. This technique is most appropriate for planning instructional programs and evaluating progress toward short-term objectives.

Penmanship. A student's handwriting must be legible for a message to be effectively communicated. In the early grades, a great deal of classroom writing instruction may be focused on writing legibility (Graham, 1982). Student writing can be evaluated to determine if it contains appropriate (a) spacing between letters and words, (b) letter size, (c) alignment (i.e., proportion of parts of letters in relation to the top, middle, and bottom line), (d) line quality (i.e., pressure consistency), (e) letter slant, (f) letter formation (i.e., correctly formed upper and lower case letters and discrimination when and when not to capitalize), and (g) style (i.e., cursive vs. manuscript). When assessing handwriting, it is important to find out what form of handwriting is expected in the classroom (e.g., D'Nealian handwriting) as well as the type of paper used for writing projects (e.g., wide ruled, college ruled). Assessment results are most useful for planning instruction and evaluating progress toward short-term objectives. An example of assessing handwriting is provided in Figure 4 using Cleo's writing sample.

Student knowledge of the writing process. Because a process approach to writing is increasingly emphasized in general education classrooms, assessment techniques should examine student understanding and demonstration of critical process variables. Student interviews can provide important information concerning the degree to which students have acquired the necessary background knowledge to meet classroom writing expectations. For example, students can discuss their knowledge of the stages of the writing process and the strategies they use to complete each stage. In addition, they can describe the various components included in narrative and expository text structures. To determine if students can apply their knowledge, they might edit a sample of their writing and discuss additional ways they could improve their writing (e.g., identify strengths and areas in need of improvement related to process and content variables). Similarly, if the teacher has established a peer-editing or "community of writers" program, a student might be asked to describe how they would edit a peer's story. Information gathered from these approaches can be used primarily for planning instructional programs and evaluating progress toward short-term objectives.

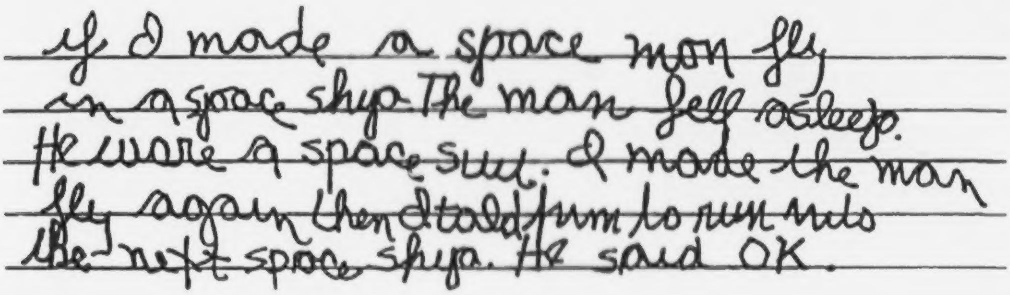
SUMMARY

Best practices in the assessment of written expression involves the systematic collection of data to facilitate educational decision making. This chapter explores the use of a problem-solving model to contextualize and guide data collection and decision making. Sources of data collection include environmental and student-performance variables. Assessing environmental variables is important to determine the writing expectations in the general education classroom, the procedures the teacher uses to teach students how to write, and which variables might be manipulated to increase student writing performance. Structured teacher interviews and classroom observational procedures are the two primary methods of gathering data on environmental variables. Direct and indirect procedures are available to collect data on student writing proficiency. Because direct writing measures provide actual samples of student writing, the results can be used to make a range of decisions including screening and program eligibility, planning instructional programs, monitoring student progress, and evaluating the effectiveness of writing programs and interventions. Many methods are available to analyze direct measures of student writing performance. The specific method or methods chosen should reflect the purpose of the assessment,

FIGURE 4. Cleo's writing sample assessed using techniques related to penmanship.

Cleo, Grade 5

I looked around the space capsule and …



If I made a space mon fly in a space ship. The man fell asleep. He ware a space suit. I made the man fly again then I told him to run nito the next space ship. He said OK.

Alignment
Cleo's mid-line, tail-line, and headline alignment look properly displayed on this sample. The letters that go to the headline could be raised and the footline alignment could use additional work.

Line Quality/Spacing
Cleo applies pressure evenly and spacing between letters is good. Left hand margin used consistently.

Beginning and Ending Strokes
Cleo uses correct beginning and ending strokes for most letters. The ending stroke for "y," beginning stroke for "t" when at the beginning of the word, and "a" could use some work.

Connections
Cleo does a nice job with words that utilize the flow between letters (e.g., fly, run). In words that require Cleo to make trace back connections, his technique is not as smooth (e.g., again, space).

Slant
Cleo's writing is inconsistently slanted. Most of his lettes are written very vertical. In addition, the spacing between lettes is more consistent than it is between words.

Letter Formation
Cleo displays some good skills in forming cursive letters. It is not clear whether Cleo has been taught all the capital letters in cursive. He appears to write in manuscript when a letter is not known (e.g., T, H, x, and s). Letters that could use some work include a, f t, and i.

ANNOTATED BIBLIOGRAPHY

Howell K. W., Fox, S. L., & Morehead, M. K. (1993). *Curriculum-based evaluation: Teaching and decision making* (2nd ed.). Pacific Grove, CA: Brooks/Cole.

The authors of this book discuss assessing student performance based on a functional teaching-oriented evaluation. Of particular interest are the chapters related to language, written expression, and written mechanics. For each chapter, flowcharts are provided to guide data collection and decision making. Each flowchart includes procedures, decisions, and teaching recommendations. This book is highly recommended for school psychologists and teachers.

Bradley-Johnson, S., & Lesiak, J. L. (1989). *Problems in written expression: Assessment and remediation.* New York: Guilford Press.

This book examines a variety of approaches for the evaluation and remediation of writing problems. Chapter topics include: (a) handwriting, (b) capitalization and punctuation, (c) spelling, (d) vocabulary and word usage, (e) sentence and paragraph structure, (f) production and quality, and (g) remediation of writing problems. The authors provide useful checklists, interview forms, and considerations for assessing student writing samples. A review of 13 norm-referenced tests and 6 criterion-referenced tests is provided in the appendix

Englert, C., & Mariage, T. (1992). Shared understandings: Structuring the writing experience through dialogue. In D. Carnine & E. Kameenui (Eds.), *Higher order thinking* (pp. 107–137). Austin, TX: Pro-Ed.

This chapter provides a good description of environmental components that are likely to lead to student success in developing writing skills. Numerous intervention ideas are imbedded throughout the chapter, related primarily to the writing process and making the components of different text structures explicit. Particular attention is paid to strategies that can used with difficult-to-teach students and ways teachers can improve the writing atmosphere in their classrooms to make writing more enjoyable and beneficial for all students.

Berninger, V. W., & Hooper, S. R. (Eds.). (1993). Preventing and remediating writing disabilities: Interdisciplinary frameworks for assessment, consultation, and intervention (Mini-series). *School Psychology Review, 22*(4).

This mini-series addresses issues related to the assessment of, and interventions for, writing problems from multiple perspectives. A strong focus is placed on prevention of writing problems and the use of assessment and remediation techniques that stem from a theory-driven model of writing development. Articles include a discussion of the relation between oral and written language, evidence of writing problems among middle-school students, and a multilevel diagnostic procedure to assess writing performance. In addition, two articles on interventions address the use of student self-regulated procedures to monitor writing performance and the use of word processors and integrated instructional strategies to increase student proficiency.

Best Practices in Assessing Mathematics Skills

Christopher H. Skinner
Mississippi State University

Hannelore H. Schock
The University of Alabama

OVERVIEW

The majority of students referred to school psychologists are experiencing mild learning problems. Although the most common learning problems faced by students are related to reading, McCleod and Armstrong (1982) found that over 66% of the students with learning problems experience some deficits in mathematics. In an effort to prevent and remedy students' mathematics skills deficits, educators, school psychologists, and researchers have attempted to develop alternative assessment procedures. These procedures have been designed to assess students' current skills, monitor students' progress through sequential curricula objectives, assess retention of mastered skills, and lead to more effective and efficient interventions and instructional procedures.

BASIC CONSIDERATIONS: MAT TEACHES HIS TEACHER

The following scenario is loosely based on one of the authors' experiences with a student. Mat, a 10th-grade student with learning disabilities and behavior disorders, was placed in a special education resource room approximately 13 weeks into the school year. Mat had been receiving educational services via homebound instruction. Mat's individualized education program (IEP) recommended beginning Mat's instruction about halfway through the fourth-grade-level curricula. This recommendation was based on Mat's 4.5 grade-equivalent score on a standardized achievement test administered less than 3 weeks before Mat arrived at the resource room. Mat's teacher obtained a copy of the fourth-grade text, workbook, and test booklet. When Mat's teacher showed Mat which book he would be placed in, Mat became angry. He stated that he had the same book in fourth grade and that his younger sister had finished this same book 2 years ago. Mat refused to start at the middle of the fourth-grade book.

Best practice indicates that assessment procedures, techniques, and materials be selected according to their purpose. Standardized, norm-referenced achievement tests are often used to help determine if students are eligible for special education services. Standardized tests are often selected based on their psychometric properties (reliability, validity, normative sample). However, as school psychologists attempt to become involved in activities designed to prevent and remedy students' problems, the weaknesses of standardized achievement testing procedures become more evident.

Standardized mathematics achievement tests primarily assess accuracy on mathematics operations. Most mathematics curricula include over 100 separate, sequential skills to be mastered between grades 1 and 8. Across curricula publications, the objectives and sequence of objectives may vary. Shriner and Salvia (1988) compared the objectives across two different curricula and found that the Distar curricular objectives differed significantly from the Scott-Foresman curricula objectives for grades 1–3. In addition, they found what they termed a "chronic non-correspondence" between the objectives of these curricula and the assessment items on the Key Math Diagnostic Arithmetic Test and the Iowa Tests of Basic Skills. Given this lack of overlap between test items and curriculum objectives, standardized test results should not be used to assess students' ability to learn mathematics because students have not been taught all of the skills assessed. These assessment devices also neglect assessing other skills that have been taught.

Standardized, norm-referenced, achievement testing procedures have several other weaknesses. First, it is impossible for these one-shot assessment procedures to adequately assess the large number of mathematics skills taught across grades 1–8 because they cannot provide enough opportunities for students to perform those skills. Second, because assessment responses are often presented in multiple-choice format, students may respond correctly to some items they have not yet mastered. Finally, although standardized achievement tests assess student ability to perform mathematical operations, most tests do not allow for assessment of other mathematics skills including fluency, adaptation, and generalization. Due to the poor overlap with instructional objectives and the limited scope of skills assessed, standardized mathematics achievement tests do not provide enough data for determining students' learning rates or identifying skills that have been mastered and skills that require additional instruction.

Most curricula include assessment materials (text-provided practice tests and assignments; workbook practice tests and assignments; and test booklets for chapters, units, and grade levels) which have several advantages over standardized, norm-referenced achievement tests. First, these materials provide assessment of skills in a sequence that matches the curricula. This prevents teachers from assuming students have mastered prerequisite skills that have not in fact been mastered or maintained. Second, curricula-provided assessment materials often contain page numbers that allow one to easily and quickly determine which objectives require remediation and where they are covered in the curricula. Third, because some tests only assess one grade level, one chapter, or several chapters (often called units), a larger sample of students' performance across a more limited range of skills can be obtained. Fourth, the responses to these items are not multiple choice and therefore prevent concluding that students have acquired skills when they guessed or estimated correct answers. If students are asked to show their work on these assessments, some permanent product-assessment data are gathered that may reveal error patterns and therefore lead to more effective and efficient interventions. Finally, because the curricula contain many different sources of assessment across skills, teachers may be able to obtain multiple assessments of student performance across each skill allowing the teacher to monitor students' progress and performance through curricula objectives and assess the maintenance of skills learned.

Mat was angry because he was placed in a text which he had completed several years ago, but his case is not unique. Many students with mathematics skill deficits have mastered some skills targeted at various curricula levels throughout their education but failed to acquire other skills at similar levels. These mastered skills are sometimes called splinter skills. Although standardized assessment results show that Mat is functioning at a 4.5 grade level, Mat probably has mastered many skills in the fourth-grade and subsequent curricula. Mat is already behind in mathematics achievement and needs to spend instructional time improving his proficiency on skills he has not mastered, rather than working on objectives he has mastered and maintained. In addition, Mat may not possess all the skills assumed to be mastered in the earlier curricula. Because many mathematics skills require mastery of earlier, prerequisite skills, Mat may have difficulty mastering some objectives in the fourth-grade curriculum. Mat was motivated to learn new material. By placing Mat in the 4.5 curricula the teacher risked ruining Mat's motivation and occasioning behavior problems by requiring Mat to work on skills he has already mastered or can not perform because he lacks the prerequisite skills.

The teacher could have attributed Mat's anger to his emotional problems and/or learning disability and attempted to begin teaching Mat at the 4.5 level. Instead, the teacher met with the school psychologist to discuss Mat's case. The school psychologist and the teacher used curriculum-based measurement procedures to determine Mat's placement within the curricula and monitor his progress through curricula objectives.

BEST PRACTICE IN PROGRESS GRAPHING: AN APPLIED SOLUTION

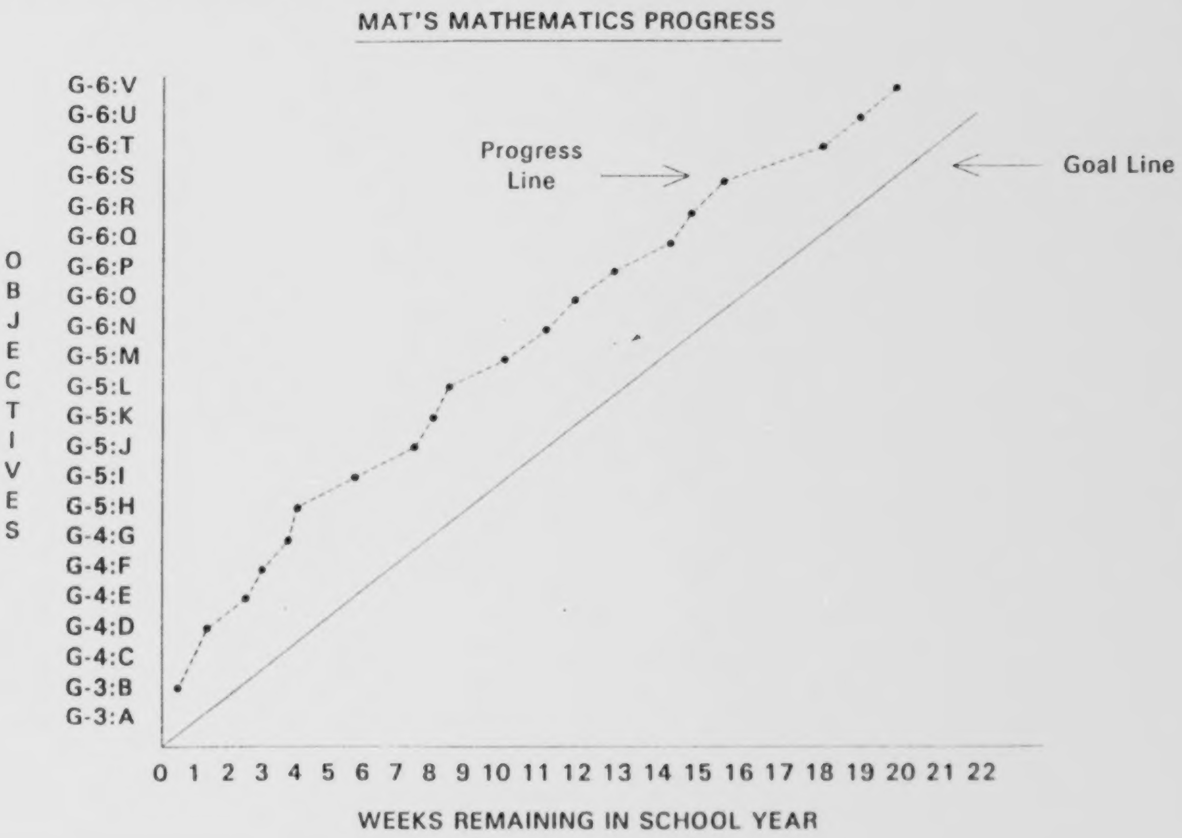
Before any instruction began, Mat's teacher had to identify which curricula objectives Mat had mastered and which he had not. The most readily available source of assessment materials was contained within the mathematics curricula.

During the next two mathematics class periods, Mat completed the end of book tests for grades 3–6. These tests were taken from workbooks. Based on Mat's errors on items which assessed specific objectives, the school psychologist constructed a sequential list of objectives for Mat from the curricula for grades 3–6. For grade 3 there were two objectives, for grade 4 five objectives, for grade 5 six objectives, and for grade 6 nine objectives. These 22 objectives comprised Mat's instructional objectives. Mat and the school psychologist then constructed a progress graph to monitor Mat's progress through the curricula (Fuchs, 1989).

Figure 1 shows Mat's progress graph. The objectives are assigned letters and listed in sequence on the vertical axis of the graph. The horizontal axis shows the remaining 22 weeks of school. In Figure 1 the broken line represents Mat's progress through curriculum objectives and the solid line represents Mat's goal or aim line. The school psychologist showed Mat how to monitor his progress using this graph. Mat was taught to place a dot on the graph when objectives were mastered and fill in the progress line. This ritual served as a stimulus for the teacher to reinforce Mat socially for his mastery of objectives and allowed Mat to self-monitor his rate of progress through curriculum objectives.

Before beginning to teach instructional objectives, Mat's teacher used the unit test (units were comprised of three or four related chapters) to ensure that Mat had mastered all the other skills contained within the unit which contained Mat's first ob-

FIGURE 1. Mat's progress graph.



jective (subtracting three-digits from three-digits with borrowing) and second objective (subtracting four-digits from four-digits with borrowing). Mat correctly completed all of the items in this unit, except when borrowing from 0 was required in the tens and/or hundreds column. Mat's teacher began to teach the procedures and rationale for borrowing when a 0 was in the tens column. About 2 minutes into the direct instruction Mat responded, "Oh, yeah, I remember this!" and successfully completed this type of problem. Mat's teacher instructed Mat to do another problem and verbalize the steps and rationale for these steps. Mat completed these tasks successfully. Mat's teacher then gave Mat a four-digit minus four-digit problem with 0's in the tens and hundreds columns. Again Mat completed this problem accurately and explained each step.

Mat was more excited than his teacher. Mat's teacher assigned 20 subtraction problems for in-class work. Some problems contained subtraction with borrowing, some did not. Some problems had 0's in the tens and/or hundreds column, others did not. Mat finished all these problems in 10 minutes, and all were accurate. Mat was given the practice tests from the ends of chapters 10 and 12 for homework. Chapter 12 was assigned because it contained subtracting four-digits from four-digits.

Before leaving, Mat told his teacher that he liked this system but would prefer not to take the text home because he would be embarrassed if his family saw he was placed in the same text his younger sister finished 2 years ago. Mat's teacher changed his assignment to the practice test in his workbook, removed these assessments from Mat's workbook, and gave them to Mat to take home. When Mat returned the next day, his teacher checked his work, found that Mat had completed it accurately, and gave Mat three in-class tests (the chapter 10 test, the chapter 12 test, and the end-of-third-grade test). Mat scored 100% on all, graphed his mastery of the first two objectives, turned in his grade 3 materials, and began similar test-teach-test procedures for grade 4 objectives the next school day.

Mat's situation appears to be a best case scenario. However, students with mathematics skills deficits can re-acquire objectives with little direct instruction. Mat probably spent substantial amounts of time learning borrowing from 0's earlier in his education.

Unfortunately, he did not master and/or maintain these skills. However, his previous instruction made it easy for him to re-learn these skills. Further, remedying his inaccuracies in borrowing 0's from the tens column also helped remedy his problem with borrowing 0's from the hundreds column. Because mathematics objectives are sequenced and assume students have prerequisite skills, often problems missed later in the sequence are caused by failure master or maintain skills targeted earlier.

If Mat were to continue to progress at this rate, he could be expected to acquire all objectives in 44 school days. This should not be expected. Students with splinter skills often make rapid progress with little direct instruction in the early skills. However, as higher level material is covered, mastery of objectives may be slowed.

Figure 1 shows how Mat's progress slowed s he began to learn higher level skills. However, he successfully attained all his objectives through grade six before the school year ended. The next step would be to assess grade seven and possibly grade eight objectives using the same end-of-text, end-of-chapter, and end-of-unit tests.

When students are failing to make progress or master objectives, the difference between goal lines and progress lines can signal teachers to alter instructional techniques so that students can reach year-end goals (Fuchs, 1989). Typically, a vertical line is drawn on the graph at the point where new instructional procedures are implemented. By comparing the slope of the student's progress line before and after new instructional techniques are added, the relative effects of instructional procedures can be evaluated (Fuchs, 1989). However, the slopes of the progress lines only provide a rough estimate of relative learning rates under the different instructional procedures because the target behaviors differ as students progress through curriculum objectives.

Because it is impossible to predict an individual's rate of learning across each and every objective, goal lines are not fixed. Original goal lines can be altered when students are making progress much faster than anticipated (objectives can be added yielding a steeper goal line). When students are progressing much slower than anticipated, objectives can be subtracted (flatter goal line). Fuchs (1989) suggests that using consistent rules for altering goal lines may result in increases in progress rates. However, researchers have not clearly indicated which rules result in the greatest increase in progress. Since the unit of measurement is an individual student's progress, it is not likely that any one decision rule for altering goal lines and changing instructional interventions will result in the highest rate of learning for all students across all objectives.

Figure 1 shows that Mat's progress was always above the goal line. However, a new progress graph with additional objectives and a steeper goal line was not constructed because the graphs and the process of progress graphing seemed to be motivating Mat. Mat often commented to his teacher and would show other students and school personnel his progress graphs indicating that he was ahead of his academic goals. Mat's teacher felt that it was important to keep Mat confident and enthusiastic about his progress through mathematics objectives. Therefore, goal lines were not adjusted but the teacher continued to attempt to keep Mat's progress ahead of his goal line.

Mat's problem is not unique. Many students with difficulties in mathematics have mastered some skills and not others. The causes of this can include being absent or not paying attention when material was covered, failing to retain material previously mastered, paying poor attention due to family problems, having different curricula covering different objectives in different sequences, and so forth. For Mat and his teacher, uncovering the causes of Mat's failure to learn was not the primary goal. Rather, the goal was to determine which skills had been mastered and retained and which had not. Mat was already behind in mathematics achievement. The standardized test showed this. However, the test did not pinpoint which skills needed to be targeted for remediation.

If Mat were placed in the 4.5 curriculum, as his standardized test score indicated, he was likely to experience problems with other mathematics skills that require borrowing from 0. Through these assessment procedures Mat's teacher was able to teach only those skills which required remediation and was able to skip skills and even entire chapters of curriculum objectives. Repeated curriculum-based assessments using chapter, unit, and end-of-book tests from workbooks, textbooks, and test booklets allowed Mat to practice skills that he had mastered. In addition, Mat's graphing his progress through the curriculum may have helped keep Mat motivated. These graphs also allowed Mat's teacher to evaluate the effects of different instructional interventions.

BEST PRACTICE IN ASSESSING MASTERY

Stages of Learning

In Mat's case, curricula materials (end-of-chapter questions, units, text tests, workbook practice test, and test booklet test) were used to assess his mathematics skills. However, mathematics curricula have been criticized for lacking in scope of skills and concepts covered and assessment of those skills and concepts (Hopkins, 1986). Mastery of mathematics skills implies being able to do much more than solve rote and meaningless computation problems. Haring and Eaton (1978) describe a learning hierarchy where the first stage of learning is acquisition and the goal is to increase accuracy. Traditionally, teachers and school psychologists have concentrated solely on assessing students' accuracy on mathematics problems. However, if the goal is for students to learn socially valid mathematics skills, they must also be able to respond accurately and quickly. This second level of learning involves increasing students' speed of accurate responding. Haring and Eaton (1978) call this *fluency*. After increasing students' accuracy and fluency, teachers and educators must ensure students can discriminate when these skills should be applied and when they should not be applied. Haring and Eaton (1978) call this the *generalization* stage of learning. If students can only respond accurately to printed numerical problems, then they are not likely to generalize these skills to applied situations. Haring and Eaton's (1978) final stage of learning is adaption. Students who can adapt their responses can go beyond what they were taught directly. These students have the ability to apply principles and procedures to new problems in novel ways. Some educators call this constructing new knowledge. A final measure of learning is maintenance. If students can not maintain increases in accuracy, fluency, generalization, discrimination, and adaption, then all the learning taking place inside the classroom will not be useful in building new skills or applying skills in natural situations. Mastery of mathematics skills requires students to be able to perform all of these tasks, not just complete numerical operations accurately.

Assessing Speed of Accurate Responding

Curriculum-based measurement procedures have also been developed for monitoring student performance. Performance goals are based on fluency or speed of accurate responding (Marston, 1989). Increasing students' speed of accurate responding is important for several reasons. Students who can perform basic addition, subtraction, multiplication, and division facts both accurately and rapidly may require less effort to make these responses than those who require more time or artificial prompts to complete these tasks. Horner and Day (1991) have shown that responses requiring less effort are more likely to be made than responses requiring more effort. Therefore, students who can respond both accurately and rapidly may be more likely to use these skills in classroom and applied environments.

Students who must count on their fingers to solve 1 digit by 1 digit times tables are faced with a long and arduous task when they must complete 10 multiplication problems with multiple digit factors (i.e., 6874 x 3957 =). Students who can perform basic addition and multiplication operations quickly and accurately may receive a larger number of opportunities to practice the new steps involved in solving these complex, multistep problems. These additional and higher rate opportunities to respond may increase students' acquisition, fluency, and maintenance of higher level mathematics skills. These additional opportunities to respond also allow these students more exposure to trials designed to promote generalization, discrimination, and adaption.

Cognitive information processing theorists use the term *automaticity* to describe this goal of increasing speed of accurate responding. Some cognitive scientists believe that if skills are practiced, students will take less time to complete responses accurately and require less cognitive processing capacity and attention (Hasselbring, Goin, & Bransford, 1987). If skills are automatic, more cognitive attention is available to apply to other tasks, such as learning a complex new skill requiring students to perform these basic prerequisite skills. In the previous paragraph's multiplication example, the student is required to learn the steps to solving multidigit multiplication problems. However, if the student is spending so much time and cognitive energy working the basic facts, little energy can be devoted to learning the new steps or algorithms for solving the multistep problems.

Assessment of automaticity for specific facts. Speed of accurate responding has been measured in several ways. Hasselbring and Goin (1986) developed a computer program that measures speed of accurate responding to basic mathematics facts. Hasselbring, Goin, and Bransford (1987) describe a similar procedure for measuring automaticity in basic mathematics facts using flashcards. Using this system, students are shown a flashcard with a basic problem (e.g., 6 + 3 =). The student is observed and response time recorded. When students respond accurately within 1–2 seconds they are considered automatic. When student responses take longer or they use obvious counting strategies, they are considered nonautomatic. These procedures can then be used to assess automaticity across each and every basic mathematics fact.

If the digits 0–9 are considered the basic fact pool, a 10 x 10 matrix emerges for each basic operation (multiplying, dividing, subtracting, and adding). Because these four one-digit by one-digit operations are required for most higher level mathematics operations, it is important for students to become automatic or fluent in these skills. However, assessing 360 different facts in isolation is time consuming, especially if a computer is not available. One way to increase the efficiency of these assessments would be to have students assess each other. Another procedure would be to present mathematic fact problems to the entire class every two seconds.

Assessment of fluency for general problems. Curriculum-based measurement procedures provide a more molar system for evaluating speed of accurate responding (Marston, 1989). Under this system, students are given assessments containing many different computation problems. Students are timed and their number of digits correct per minute is calculated. A digit is considered correct if the correct numeral appears in the correct column. For example, if the problem is 6 x 8 = , a response of 48 is scored as two digits correct. A response of 84 is scored as two digits incorrect, and responses of 42 or 78 would both be scored as one digit correct and one digit incorrect. Any skipped digits or problems are scored as incorrect. Only digits that occur after the equals symbol are counted. The number of digits correct per minute is then calculated by dividing the total number of digits correct, multiplying by the number of seconds required to complete the problems and dividing by 60 seconds.

By providing time limits and a large number of problems, curriculum-based-measurement procedures allow teachers to assess the fluency of large groups of students. For example, students could be supplied with sheets containing 100, one-digit by one-digit multiplication problems and instructed to complete as many problems as they can in 1 minute. After 1 minute, teachers can collect all of the sheets and determine each student's accuracy and fluency levels. Because fluency measures are very sensitive, if a student makes one mistake and goes back to correct it, much time is lost and his number of digits correct per minute will be dramatically reduced. Therefore, three separate assessments should be conducted and median scores should be used as fluency measures. These measures can be used to assess one set of skills (i.e., one-digit by one-digit multiplication) or multiple skills (addition, subtraction, and multiplication).

Deno and Mirkin (1977) supply some normative data on students' fluency. In grades 1–3, 0–9 digits correct per minute or 8 or more errors per minute is considered frustrational level. Mastery of a skill is obtained when 20 or more digits are correct per minute with 2 or fewer errors per minute. In between these levels are instructional levels. In grades 4 and above, mastery requires students to complete 40 or more digits correct per minute with frustrational level below 20 digits correct per minute. In grades 4 and above the error criteria are the same as for grades 1–3. Interested readers can find additional curriculum-based-measurement normative data in Shapiro (1989). Fuchs and Shinn (1989) provide procedures for developing local normative data. Local norms can be used to determine an individual student's performance in relation to other students in specific classrooms. These norms can be used to help set IEP goals and as criteria for determining readiness for placement in specific classrooms or general grade-levels placements (Fuchs & Shinn, 1989). When the school psychologist assessed Mat's performance on the end of book test, Mat was also given separate skill probes for basic addition, subtraction, multiplication, and division. Median scores across these probes showed that Mat was working at mastery levels on addition and subtraction but was functioning at instructional levels in multiplication and division. Results of these assessments showed that Mat made very few errors in multiplication and division, but his digits correct per minute fell between 20 and 30. Therefore, the school psychologist and Mat's teacher developed several procedures designed to increase Mat's rate of accurate responding across these areas. Graphing procedures similar to those employed for Mat's progress monitoring were used to evaluate the effects of these interventions and determine when Mat had reached his fluency goals. Marston (1989) provides a detailed description of the procedures for progress monitoring.

Assessing Discrimination, Generalization, and Adaption

If students are to use mathematics skills in applied situations, they must be able to do more than perform mathematics operations on numerical problems containing signs and symbols. Students must also be able to discriminate when specific operations are required and when they are not required. One danger in the program designed to remedy Mat's mathematical skill deficits is that many of the skills may be taught in isolation. When students learn concepts and procedures in isolation, they may not be able to apply these appropriately to novel or even similar context because they have not acquired an understanding of the interrelatedness of the mathematical ideas (Hopkins & Dorsey, 1992). Successful problem solvers are able to perform procedures correctly and also choose appropriate procedures in which to engage (Herman, 1992).

In Mat's case, if the teacher had concluded that Mat had mastered different procedures based solely on his accuracy on specific numerical operations, the teacher would have run the risk of teaching Mat only mathematics operations. Rather, the teacher used other assessment procedures to determine if Mat had obtained an understanding of these concepts which will allow him to determine when these operations should be performed and when they should not.

One way to help determine if students have acquired the ability to generalize and discriminate is to assess students' performances on problems requiring newly learned skills while also assessing their performance on similar problems which require different, already mastered operations. In Mat's case, the teacher used end-of-chapter, end-of-unit, and end-of-grade tests to assess Mat's mastery. These tests are superior to assessments which target only single skills because they typically require different operations on similar problems.

Assessments contained within the curricula may provide some indication of students' ability to generalize and discriminate. However, mathematics textbooks have been criticized for teaching primarily logarithmic numerical operations and not providing enough instruction or assessment of students' ability to apply skills to novel situations (Remillard, 1992).

Therefore, teachers and school psychologists may want to supplement both their assessment and instructional procedures with additional activities.

Teacher-constructed tests. Teachers and school psychologists can use a variety of assessment procedures to determine whether students have gained enough understanding of mathematics concepts to generalize, discriminate, and adapt those concepts. One procedure is for teachers to construct their own written assessments. More than simple operations, problems should also include word problems, graph or figure problems, and applied problems that have some meaning to students. Before constructing these items teachers must ensure that students have the prerequisite skills necessary to comprehend word problems and interpret graphs, figures, and the like. Teacher-made assessments should include clear direction and adequate sampling of the types of problems target skills can be generalized to, as well as problems that are similar but require students to apply different skills. Problems requiring multistep operations having more than one correct answer, and including unnecessary information also allow one to assess students' abilities to discriminate, generalize, and adapt concepts and operations. Items on these tests should be designed to give useful information not only about the product or answer but also about students' conceptual knowledge and understanding of mathematical relationships (Trafton, 1987). Therefore, students should be encouraged to show their work and adequate space should be provided so that teachers can analyze student errors and conceptual understanding.

Error analysis. Mat's teacher was able to detect a particular error pattern that Mat was having. One of Mat's deficits related to borrowing from 0. Error analysis of students' written work samples can strengthen the link between ongoing daily assessment and instruction. Often teachers assume that students miss problems because they do not know their basic facts when actually students are making procedural errors. Remediation may be more successful when the specific error patterns can be identified, especially if these error patterns are identified and corrected before these patterns become ingrained. Because some errors are random and/or caused by basic computation errors, at least three to five examples of a type of problem should be present in a sample in order for an error pattern to surface (Fowler, 1978; Hopkins, 1986). Again, it is important that enough work space be provided so that the teacher can easily analyze students' procedures.

To ease the task of detection, several authors have listed common errors (Ashlock, 1983; Enright, 1990; Hopkins, 1985). Becoming familiar with these common errors can enhance and accelerate the error analysis and remediation process. Hopkins (1986) suggests using an error pattern matrix to make error analysis more efficient. This involves creating a matrix for a particular test or assignment and anticipating the incorrect answers that students will give on each specific problem if they fall prey to particular error patterns. For example, students often have difficulty borrowing. If a student answers 14 to the problem 23 − 17 = ________, the student may have subtracted the larger number from the smaller number in the ones column. While grading, the teacher can quickly determine which error patterns are evident for individuals as well as groups of students by simply looking at the incorrect answers and noting the specific error pattern (Hopkins, 1986).

Error analysis procedures are not limited to basic arithmetic computations. Fowler (1978) describes error analysis procedures for tasks as varied as geometry and statistics. Neither should this activity be limited to a focus on algorithms. Sometimes students miss problems because of a limited number or inappropriate use of strategies in their repertoire.

Interviews. Analyzing students' written calculations for error patterns can suggest interventions, but sometimes written work does not reveal the extent of the student's thinking (Szetela & Nicol, 1992). Mathematics interviews are one tool for assessing a student's problem-solving strategies and gaps in conceptual knowledge. Requiring students to verbally communicate their problem-solving steps may assist teachers in assessing appropriate and inappropriate problem-solving strategies.

Interviews can involve simply asking students to explain the procedures they used in solving a particular problem and what the answer means, as was done for Mat. Interviews can also be detailed and structured. Guidelines for conducting these interviews have been described by Lindquist (1988), Labinowicz (1987), Bartel (1986), and Hammill and Bartel (1982). These guidelines include starting interviews with problems that students have already mastered to build students' confidence, audio-taping interviews to obtain permanent product data, and allowing students to describe their thinking and problem-solving behaviors using their own words rather than specific terminology in order to avoid stifling, interrupting, or discouraging their thinking and description of thoughts. Some students may rush the interview process by giving the teacher what they feel is the desired information in order to please the teacher. For this reason, interviews should be conducted in a manner free from judgment and hints about correct responses.

Activities-based assessment procedures. Mathematics problem solving can require a great deal of higher order thinking, but it is often difficult for students to communicate both verbally and nonverbally how they solved a problem (Szetela & Nicol, 1992). Therefore, educators may need to provide some activities designed to help students identify and communicate their covert thinking behaviors.

Wadlington, Bitner, Partridge, and Austin (1992) suggest using other specific activities designed to help students express their covert problem-solving behaviors. These activities include asking students to write explanations and justifications of their procedures as a part of the problem-solving process and having students keep mathematics journals for personal reflections about their abilities and reactions to specific problems.

Other data which can help determine students' understanding of mathematics relationships can be gained by engaging in classroom discussion about constraints and different applications of various mathematical concepts and procedures. Requiring students to generate their own examples of general areas and specific problems where concepts can be applied may allow one to assess students' understanding of mathematics concepts and their ability to generalize these concepts to meaningful situations. Requiring students to explain their cognitive problem-solving behaviors to other students using cooperative learning or peer tutoring techniques can also improve students' mathematical communication skills and provide valuable assessment data regarding students' understanding of mathematics rules and concepts (McKillip & Stanic, 1988). Students' understanding of the problem-solving process can also be assessed by asking students to analyze various aspects of problems, generate multiple alternative procedures for solving problems, and justify their solutions and their choice of procedures to arrive at solutions.

Authentic assessment procedures, which have become popular in response to the limitations of standardized tests, emphasize the potential for meaningful and rich, real-life contexts for assessment activities. Sometimes referred to as performance assessment or dynamic assessment, authentic assessment strives to achieve close ties between assessment, the curriculum, and the world outside the classroom where the skills will eventually be tested. Problems should be presented in a simulated, contrived, or natural format so that their relevance is obvious to students and requires students to go beyond isolated skill performance (Herman, 1992; Hopkins & Dorsey, 1992). Students can be allowed to use textbooks and other resources to help them find solutions (Wiggins, 1992). Though assessment of performance in this rich context is preferred, it is important to remember that emphasis on assessing the students' understanding of the concepts underlying the activities should not fall to the wayside because of an emphasis on performance outcomes.

BEST PRACTICE IN PREVENTING SKILL DEFICITS

If the goal is to prevent mathematics skill deficits, assessment procedures must be developed that allow continuous monitoring of students' mastery and retention of objectives. Mastery criteria should include more than the ability to perform mathematical operations: They should also include the ability to perform these procedures quickly, to choose appropriate operations, to maintain these skills, and to apply these skills to novel situations.

One system that allows regular education teachers to continuously assess general education students' mastery of curriculum objectives has been developed by Fuchs (1992). Under this system, students are given a test at least every 2 weeks. The tests have been constructed so that each test contains one operations and one applications problem for each objective across an entire grade level. Students are given a limited amount of time to complete the test. Teachers are then given feedback regarding each students' performance on the test. This feedback allows teachers to monitor who has mastered and maintained objectives.

Mastery includes fluency because time limits are in place. Mastery also includes generalization, discrimination, and adaption because many different application problems for each operation are provided over the course of the year. Maintenance is measured because each and every objective is assessed every 2 weeks.

This type of system is similar to curriculum-based-measurement procedures discussed earlier. A major difference is that this system uses computer-generated monitoring procedures and preconstructed assessments which allow teachers to identify students who are experiencing problems with current mathematics objectives and ensure that they get help before they fall too far behind. In addition, by repeatedly assessing earlier objectives, these tests allow teachers to monitor student maintenance of specific objectives. When individual students fail to retain specific skills, teachers can implement procedures designed to re-teach those skills before too much time elapses. This reteaching of unretained skills prevents teachers from assuming students have prerequisite skills needed to perform new objectives. Because tests are given frequently, students are also given opportunities to practice skills that have been mastered. Therefore, the assessment procedures also serve as retention drills.

SUMMARY

Recently school psychologists have begun to question the educational validity of traditional assessment procedures. Educationally valid assessment procedures are said to provide information on how to better teach students. Diagnostic error-analysis procedures described in this chapter may lead to effective interventions for specific concept and operations deficits. In addition, the methods provided here for assessing accuracy, speed, generalization, discrimination, and adaption may help educators specify the types of problems students are experiencing and suggest general procedures designed to remedy those problems. Haring and Eaton (1978) suggest different interventions for different stages of learning. Students acquiring new skills need demonstrations, models, cues, and routine drills to increase their accuracy rates. Students who are working on increasing their speed of accurate responding need repeated novel drills and reinforcement for increased rates of accurate responding. To increase students' ability to generalize new skills, training across different stimuli conditions is needed. Increasing students' ability to adapt responses can be occasioned through problem-solving training, simulation training, cooperative group techniques, and exposure to novel applied problems.

Using the assessment techniques described in this chapter may allow one to select interventions designed to remedy specific skills deficits (i.e., interventions designed to increase acquisition versus interventions designed to increase fluency). Although these types of assessment may suggest a general class of interventions, school psychologists must evaluate the effects of all interventions. Currently there is no assessment system that allows one to determine what will definitely be the most effective instructional strategy for each student (Deno, 1985). Therefore, different techniques should be tried and their outcomes must be assessed on an ongoing basis.

Retention of mastered objectives is too often assumed. One reason why students experience mathematics learning problems is their failure to maintain skills. Fuchs' (1992) system offers an efficient and practical procedure for monitoring individual student progress through objectives and maintenance of skills over time. School psychologists and other education professionals must continue to develop and refine assessment procedures that allow for repeated or continuous assessments so that educators can ensure students have maintained previously mastered skills and remedy deficits that are not mastered or maintained. In this manner, mathematics learning problems may be prevented before they become severe.

Best Practices in Vocational Assessment in the Schools

Edward M. Levinson
Indiana University of Pennsylvania

OVERVIEW

Work plays an important role in our lives. Research has suggested that positive adjustment to work is associated with increased self-esteem and a positive self-concept (Dore & Meachum, 1983; Erickson, 1968; Kalanidi & Deivasenapathy, 1980), reduced frequency of physical and mental health problems (Portigal, 1976), and increased satisfaction with one's life (Schmitt & Mellon, 1980). It is clear that the adequacy of our choice of occupation and the degree to which we adjust to work, has an impact on our overall happiness and quality of life. For this reason, it is important to ensure that individuals possess the knowledge and skills necessary for making realistic and informed career decisions, and to assist those who may be unable to make such decisions on their own. Information gleaned from vocational assessment is a critical component of this process.

The school population with whom school psychologists work most frequently, persons with disabilities, continue to be at high risk in regard to securing and maintaining employment. The President's Committee on the Employment of the Handicapped reports that only 21% of persons with disabilities will become fully employed, 40% will be underemployed and at the poverty level, and 26% will be on welfare (Pennsylvania Departments of Education and of Labor and Industry, 1986). Studies have indicated that 67% of persons with disabilities in the United States between the ages of 16 and 64 years are not working (Harris & Associates, 1986; Rusch & Phelps, 1987). Of those who are working, 75% are employed on a part-time basis, and of those who are not employed, 67% indicated that they would like to be employed. Similarly, statewide surveys in Florida (Fardig, Algozzine, Schwartz, Hengel, & Westling, 1985), Washington (Edgar, 1987), Colorado (Mithaug, Horiuchi, & Fanning, 1985), Vermont (Hasazi, Gordon, & Roe, 1985), and Nebraska (Schalock & Lilley, 1986) have indicated that the employment rate for persons with disabilities ranges between 45% and 70%, depending upon disability and geographical location. Between 64% and 82% of this population report living at home with a parent or guardian.

More recent data corroborate these findings but suggest some encouraging trends as well. D'Amico and Marder (1991), in a longitudinal study that included a nationally representative sample of youths with disabilities out of school at least 1 month and no more than 2 years, reported that 52% of youths with disabilities were employed in 1987. However, this employment rate had increased to 67% in 1989. While employment rates had increased in almost all disability categories, the rates varied by disability category. Although 67% of learning-disabled persons were employed in 1989, only 48% of emotionally disturbed, 56% of mildly and moderately retarded, and 10% of multiply handicapped youths were reported to be employed (Marder & D'Amico, 1992). In all disability categories other than learning disability and speech impairment, the employment rates of youths with disabilities was significantly lower than the employment rate of nondisabled youths (Marder & D'Amico 1992).

In addition to the high unemployment and underemployment rates, persons with disabilities also demonstrate an elevated high school attrition rate. Edgar (1987) reports that 42% of students with learning and behavioral disabilities leave school before graduating, as do 18% of mentally retarded students. More recently, the *Twelfth Annual Report to Congress on the Implementation of the Education of the Handicapped Act* (U.S. Department of Education, Office of Special Education and Rehabilitative Services, 1990) indicated that 47% of all students with disabilities do not graduate from high school with either a diploma or certificate of completion. These data are corroborated by data gathered by Wagner and Shaver (1989), who found that 44% of students with disabilities failed to graduate from high school and 36% of the students with disabilities dropped out of school.

There is little doubt that, given the high unemployment and underemployment rates among persons with disabilities, the high percentage who continue to live at home, and the elevated dropout rate of students with disabilities, efforts in the area of special education have not resulted in their successful integration into society. The resulting economic cost to society is staggering. Published reports have suggested that 15 million of the 16 million unemployed, noninstitutionalized disabled persons of working age were employable at a potential cost savings of $114 billion per year (Poplin, 1981; Batsche, 1982). The social, physical, and emotional benefits to be gained by persons with disabilities from successful adjustment to work are not to be eclipsed by consideration of the economic benefits to be derived by society. Just as successful adjustment to work is likely to be accompanied by increased feelings of self worth, greater overall life satisfaction, and a higher quality of life among the non-disabled population, so too are these likely to be benefits derived by those with disabilities.

To address the problems just outlined, considerable legislation designed to improve the vocational and career assistance provided to persons with disabilities has been passed in the last 10–15 years. The Vocational Rehabilitation Act, the Education of the Handicapped Act, the Vocational Education Amendments Act, and the Career Education Incentive Act have combined to provide federal funding assistance to assist those with disabilities to prepare for work.

More recently, the Carl D. Perkins Vocational Education Act, and the Individuals With Disabilities Education Act have contributed to the development of vocational and career assessment services in the schools. The Perkins Act requires that information about vocational education opportunities be provided to parents and students no later than the beginning of the ninth grade or at least 1 year before the student enters the grade in which vocational education is offered. The act also requires that information about eligibility requirements for enrolling in vocational education programs be provided to parents and students and that, once enrolled in vocational education, students receive an assessment of interests, abilities, and special needs and other special services designed to facilitate transition from school to postschool employment or training.

The Individuals with Disabilities Education Act (IDEA) was passed in 1990 and reauthorizes and expands many of the provisions of Public Law 94-142 (the Education for All Handicapped Children Act). IDEA incorporates requirements for the establishment of services designed to assist students in making a successful transition from school to work and community living. Under this law, plans for a student's transition from school to work and community living must be initiated by age 16. Readers who are interested in additional information on transition services are referred to the chapter on transition by Levinson elsewhere in this volume.

For the purposes of this chapter, the terms *career assessment*, *vocational assessment*, *vocational evaluation*, and *work evaluation* will be considered synonymous, although distinctions have been made among them in the literature. While the purpose of all of these processes is to generate information that can be used to assist the individual in making decisions regarding career choice, their differences have largely to do with the professional group involved in the process, the setting in which the process occurs, or the instrumentation or methodology utilized to complete this process.

School psychologists report spending only a small percentage of their time in vocational activities despite attaching great importance to them (Shepard & Hohenshil, 1983). Studies have indicated that approximately one third of school psychologists have had some involvement in vocational assessment (Levinson, 1988). Regardless, NASP has provided considerable support for school psychologists' involvement in vocational activities, and it incorporates both vocational assessment and vocational intervention in its *Professional Conduct Manual*.

In its description of Standards for the Provision of School Psychological Services, NASP (1992) prescribes that "psychologists and psychoeducational assessments include evaluation, as appropriate, of the areas of . . . vocational development, aptitude, and interests" (p. 44).

In reference to consultation, the standards state that "school psychologists provide skill enhancement activities (such as . . . vocational development . . .) to school personnel, parents, and others in the community, regarding issues of human learning, development, and behavior" (p. 44). As to direct services, the standards specify that "School psychologists design direct service programs to enhance . . . vocational development" (p. 45).

Hence, if school psychologists are going to practice their profession in a manner consistent with their professional standards, they *should* be involved in vocational assessment and programming in the schools. In fact, given their particular expertise as compared with that of other professionals in the schools, the school psychologist's involvement in the vocational assessment process may be critical to the success of such programs. The school psychologist's psychometric expertise and knowledge of measurement theory can safeguard against the inappropriate selection and use of assessment devices and against the inappropriate interpretation and use of assessment data (historically a problem in vocational assessment programs in the schools). Their skills in assessment can be used to generate data (e.g., in the realms of intelligence, achievement, personality, and social skills) that are critical to vocational planning; and their knowledge of learning and behavior theory, and of adolescent psychology, can be used in the effective development and implementation of services.

BASIC CONSIDERATIONS

The planning and implementation of vocational assessment services should be guided by two overriding concerns: (a) vocational/career development theory, and (b) the skills needed by individuals for successful employment. While the latter determines which traits should be assessed as part of a comprehensive vocational assessment, the former determines when these traits should be assessed and how the resulting data will be interpreted.

Vocational/Career Development Theory

Development theory underlies and guides the appropriateness of any assessment or educational intervention. Just as our interpretation of letter reversals and transpositions in writing is influenced by our understanding of perceptual–motor development (that is, we wouldn't be overly concerned about a 6-year-old who evidenced letter reversals but would be concerned about a 12-year-old who did), so too is our interpretation and use of vocational data influenced by vocational/career development theory. To design and implement a vocational assessment program for the schools, one must understand vocational development theory and use such knowledge in deciding what traits will be measured in a particular individual at any given grade or age level. Similarly, vocational development theory will allow results to be placed in perspective and will allow users of the data to generate developmentally appropriate recommendations for the student.

While there are numerous theories of vocational development, Figure 1 depicts the various stages of development that span the school years as suggested by Super (1957) and Ginzberg, Ginsburg, Axelrad, and Herma (1951). Not all individuals progress through the various stages listed at the same rate, and not all students are capable of accomplishing the objectives at each stage without assistance. One purpose of vocational assessment is to determine whether a student is progressing through the developmental stages at an acceptable rate or in fact might need assistance in accomplishing the objectives associated with each stage.

During the elementary school years, children begin to learn, through play, about themselves and the world of work. They fantasize themselves to be police officers, teachers, doctors, ballerinas, and so forth and "try on" various life roles. They also begin to learn about the value and importance of work and how to interact and work with others. As children get older and move into middle school or junior high school, self-awareness and occupational awareness are refined, decision-making skills begin to develop, and tentative interests and aptitudes emerge. In high school, students begin to combine their knowledge of themselves with their understanding of occupations and, utilizing their decision-making skills, begin to make tentative career choices.

Skills Needed for Employment

Clearly, different jobs require different sets of skills for success. For example, success as a school psychologist is more dependent upon general cognitive ability and verbal skill than it is upon manual dexterity and spatial aptitude. The opposite is true of success as a carpenter or plumber. However, there are some traits that are important for success in any employment. The ability to get along with others (social skills) and the ability to make good decisions (decision-making skills) are general skills that are important in all jobs.

A comprehensive vocational assessment incorporates an evaluation of psychological, social, educational/academic, physical/medical, and vocational functioning. Figure 2 depicts the domains that should be part of a comprehensive vocational assessment, and the information within each domain that might be gathered. It is important to note that much of the information that needs to be gathered as part of a comprehensive vocational assessment is typically obtained by school psychologists when they conduct psychoeducational evaluations. Intelligence test data, academic achievement test data, personality data, and so on all have relevance in vocational planning. As it is beyond the scope of this chapter to discuss the vocational implications of traditional psychoeducational test data, readers interested in a more detailed discussion of this are referred to Levinson (1993).

A variety of techniques are employed to collect information in vocational assessment programs. Interviews, observations, and paper-and-pencil tests are commonly employed, being techniques with which school psychologists are familiar. Additionally, performance tests, work samples, and situational assessment are often used in such programs. *Performance tests* are manipulative tasks that, while minimizing the use of language (Anastasi, 1982), are designed to evaluate a specific ability believed to be related to successful job performance. A performance task may measure manual dexterity — an ability related to the performance of many trade and technical occupations — by requiring a student to assemble a series of nuts and bolts (Anderson, Hohenshil, Buckland-Heer, & Levinson, 1990). *Work samples* are samples of actual work that allow the subject to experience work activities related to a particular job. An automotives work sample might require the subject to change the oil in a car; a clerical work sample might require the subject to file papers, type a memo, and so on. Work samples usually consist of demonstration, training, and assessment phases. The task is first demonstrated to the person being assessed; the subject is then trained to perform the task; finally, he or she per-

FIGURE 1. Developmental tasks by stage of career development age.

STAGE	**GROWTH**			**EXPLORATION**		
Substage	**Fantasy**	**Interest (What do I like?)**	**Capacity (What am I good at?)**	**Tentative (What will I do ....**	**Transition ....)**	**Trial**
Estimated age range	**0–10**	**11–12**	**13–14**	**15–17**	**18–21**	**22–24**
Tasks	1. Gain awareness of personal qualities and develop a healthy self-concept. 2. Appreciate and consider the broad variety of careers and acquire knowledge of workers, their roles, and the value of work. 3. Develop a broad, flexible, and satisfying sex role identity. 4. Develop attitudes that are conducive to competence, cooperation, and achievement.		1. Gain awareness of aptitudes and values. 2. Develop decision-making, planning, and problem-solving skills. 3. Realize that different occupations have different requirements and provide different rewards. 4. Become aware of imminent academic choices and their relationship to post-high-school alternatives. 5. Assume responsibility for own career-related decisions.	1. Gain awareness of aspiration. 2. Develop tentative career goals and identify vocational options. 3. Explore tentative career goals and vocational options.	1. Specify a choice. 2. Acquire necessary skills for entry-level employment.	1. Implement vocational choice (acquire a job).

forms the task while being observed and evaluated. Performance may be compared to industrial and age-based norms, and interest and motivation to perform the task are observed and measured. *Situational assessment* techniques are designed to test a person's interests, aptitudes, and work habits in a real or simulated work situation. A student who is interested in sales occupations might be employed in a school store and be observed and evaluated by a business education instructor. A student who is interested in a food service job might be employed in the school cafeteria and be observed and evaluated by cafeteria workers and/or an occupational foods instructor.

While not frequently employed in vocational assessment programs in the schools, curriculum-based assessment (CBA) may prove to be a particularly useful strategy in evaluating a student's potential to acquire the competencies necessary to enter or to successfully complete a vocational program. In that many vocational programs are competency-based in structure and design, these programs would appear to lend themselves to the use of CBA.

BEST PRACTICES

The following section will discuss best practices in establishing vocational assessment programs in the schools, program models that have been developed and implemented, and roles for school psychologists and other professionals in the vocational assessment process. The nature and type of vocational assessment program to be established will depend on several factors, including the available resources, the characteristics and expertise of available personnel, the population targeted for services, the nature and type of vocational and postsecondary training and placement options available in the community, and the nature of auxiliary services available.

Steps in Program Development and Implementation

The steps involved in planning and implementing school vocational assessment programs subtend three phases: planning and development; implementation; and evaluation and improvement (Levinson, 1993). Figure 3 summarizes the program development process.

The first step in program development is to set up a task force that adequately represents all school and community personnel who are likely to be involved in or affected by the assessment program. The task force conducts a needs assessment, which identifies school and community resources and services that can be utilized in the program and potential obstacles to successful vocational planning. Then an assessment model is developed that makes use of local resources and minimizes the potential obstacles. Formal interagency agreements are established between school and community agencies that clearly identify what services will be provided by which agencies, to which students, at what points in time. Funding requirements are identified, and sources of funding are secured, if necessary.

FIGURE 3. Steps involved in program development.

Phase 1 — Planning and Development

1. Develop a Task Force
2. Conduct a Needs Assessment
3. Develp a Program Model and Establish Objectives
4. Develop Local Interagency Agreements/Action Plans
5. Identify Funding Requirements and Sources

Phase 2 — Implementation

1. Hire a Vocational Assessment Program Coordinator
2. Select Vocational Assessment Site(s)
3. Develop a Procedure Manual
4. Select/Purchase Materials and Equipment
5. Train Personnel
6. Conduct Inservice Workshops with School Staff/Community
7. Pilot-Test the Assessment Program
8. Revise and Implement the Program

Phase 3 — Evaluation

1. Identify Aspects of Program in Need of Evaluation
2. Identify Standards for Evaluation
3. Hire/Identify a Program Evaluator
4. Conduct Evaluation
5. Plan and Implement Program Improvements

From *Transdisciplinary vocational assessment: Issues in school based program.* by E. M. Levinson. Copyright Clinical Psychology Publishing Co., 1993. Reprinted by permission.

A coordinator is appointed to oversee the implementation of the assessment program, who with the assistance of other involved personnel, identifies sites at which assessments will be conducted, develops a manual that clearly describes procedures, selects and purchases equipment, and trains involved personnel. Following workshops designed to acquaint school and community personnel with the program, the program is pilot-tested on a small, select target group, modified and revised, and then fully implemented.

In the final phase, after the program has been in operation for a predetermined period of time, the program is evaluated and revised as necessary.

Program Models

Most school vocational assessment programs employ several levels. At different levels, the assessment process has different purposes, uses different assessment techniques and strategies, and is designed to gather different types of information. The nature and purpose of assessment at a particular level is directly related to the developmental objectives discussed previously. Programs usually consist of either two or three levels of assessment. As summarized by Anderson et al. (1990), Level 1 assessments begin during the elementary school years, focus upon children's understanding of themselves, interpersonal skills, and decision-making skills, utilize vocational and career exploration activities, and have the goal of building self-awareness. Level 2 assessments generally occur during the middle school or junior high school years; focus on interests, aptitudes, work habits, and career maturity; utilize interviews, observations, and standardized norm-referenced assessment instruments; and have the goal of continuing to encourage career exploration and assisting students in making tentative choices regarding educational and career goals. A Level 3 assessment generally occurs during the high school years, often employs more experiential devices like work samples and situational assessment, and focuses upon the specific training needed to obtain post-school education or employment. Level 3 assessments are also designed to determine what skills a person may need in order to make a successful transition from school to work and community living.

Transdisciplinary School-Based Vocational Assessment

Transdisciplinary school vocational assessment (TVA) (Levinson, 1993) is defined as follows:

> A comprehensive assessment conducted within a school setting whose purpose is to facilitate educational and vocational planning in order to allow a student to make a successful adjustment to work and community living. The assessment is conducted by educational, community agency, and state agency personnel, in cooperation and consultation with the student's parents, and incorporates an assessment of the student's psychological, social, educational/academic, physical/medical, and vocational functioning.

The term *transdisciplinary* is used instead of *multidisciplinary* in order to depict the need to involve professionals "across disciplines" (and outside of the schools) in the vocational assessment and planning process. Figure 4 depicts the transdisciplinary school-based vocational assessment program model, which links assessment and intervention and involves school and professionals in the community in both the planning and development of the program, and in the gathering and use of data. Four phases that embody two levels of assessment are included in the TVA model. Phase 1 involves planning, organizing, and implementing the assessment program. Community agency and school personnel are involved in this planning.

Phase 2 involves an initial Level 1 vocational assessment, which is conducted at some point between Grades 6 and 9. This yields data that are used to establish educational and vocational objectives to be included in students' individual education plans. These data are used to tentatively identify vocational training options for the students — options that can form the basis for further vocational exploration. Data are also used to identify residential options for the students, curricula modifications that might be necessary to the students' success in vocational training, and school or community services the students might require to make a successful transition from school to work and community living.

Phase 3, carried out during Grades 10–12, consists of specific vocational training (which can take place in a variety of settings). Should additional problems or questions arise about the appropriateness of this training, a Level 2 vocational assessment can be conducted. Following this assessment, a revised educational/vocational plan can be developed for the student, and modifications in training can be initiated.

Phase 4 follows this training, and involves placement in a job, a postsecondary institution, and/or a residential facility. To facilitate successful transition from school to work and community living, follow-up and ongoing support can be provided as part of this phase.

A Model Developed in Virginia

The Virginia Special Education Consortium (VSEC) assessment program is a two-phase model that integrates vocational and special education triennial reevaluation processes. Federal regulations require that students in special education programs be reevaluated once every 3 years or sooner if necessary. Many of the professionals involved in this reevaluation process are the same as the personnel involved in the vocational assessment process, and much of the information can be a part of a comprehensive vocational assessment. As Levinson and Capps (1985) have noted, integrating these two processes has the following advantages: (a) It provides for a time- and cost-efficient assessment process, reduces redundant information gathering, and conserves personnel time; (b) the special education reevaluation process provides a framework for the multidisciplinary cooperation required by a vocational assessment program; and (c) integrating the vocational assessment and special education reevaluation processes ensures a holistic evaluation of the student (that is, vocational assessment will not be completed in isolation, but will be combined with psychological, educational, social, medical, and other data to provide a total picture of the student).

The VSEC's interfacing of the vocational assessment and special education reevaluation processes is described in Figure 5. A Phase I vocational assessment is conducted at the time of a student's triennial special education reevaluation (or initial special education evaluation used to identify the student as handicapped for the first time) in Grades 6, 7, or 8. All students who are identified as handicapped prior to their ninth-grade year are thus guaranteed a Phase I vocational assessment. The process is jointly conducted by teachers, counselors, psychologists, nurses, and other school personnel; it utilizes interviews, observations, and standardized tests.

A Phase II assessment is conducted during the 9th, 10th, or 11th grades upon referral only. It is conducted at a regional vocational assessment center staffed by vocational evaluators. This assessment is conducted over a period of 4 1/2 days and is designed for students who need additional evaluation or who might need an assessment composed of more work-oriented, experiential devices. The evaluation utilizes work samples, situational assessment, work behavior observation, and to a lesser extent, psychometric testing.

Roles for School Psychologists

The role of the school psychologist in a vocational assessment program will vary, depending upon the nature of the vocational services available in the district and the expertise of other involved school personnel. In a best-practice scenario, a school vocational assessment program similar to one of the models previously described will be in operation, and the school psychologist will be one of several school and community-based professionals involved in assessment and individual vocational planning. The school

psychologist might be responsible for gathering information regarding a student's intellectual, academic, and social functioning and for interpreting these data from a vocational perspective. The school psychologist's skills in CBA can prove to be particularly useful in both Phase I and Phase II vocational assessments. In a Phase I assessment, CBA can be used to determine if a student has acquired the academic skills requisite for success in a particular vocational program, or to estimate how long it might require a student to acquire these skills. This information can be used to help determine how realistic and appropriate a future vocational placement might be for a student. In both Phase 1 and Phase 2 assessments, school psychologists can employ CBA to evaluate the amount of time a student might need to acquire all of the competencies necessary for entry-level employment in a particular occupational area, and what modifications or interventions might promote their acquisition. As mentioned earlier, the competency-based structure of many vocational programs lends itself to use of CBA.

When working with adolescents, the school psychologist can include measures of vocational interests and aptitudes, as well as clinical interviews to gather vocationally relevant data. As team members, it is prudent for school psychologists to share their psychometric knowledge with others, in order to assist in the selection of instruments and techniques to be used and in the interpretation and use of the results. School psychologists' knowledge of learning theory and adolescent psychology also allows them to assist in individual vocational planning and to act as consultants for others who are involved in vocational programming.

Where an organized school vocational assessment program is not in operation, school psychologists might assume the lead in the development of such a program or assist others in such development. School psychologists' expertise in psychometrics can be used to design an assessment program that incorporates sound, reliable, and valid instrumentation. If the development of a comprehensive vocational assessment program involving several professionals is not possible, school psychologists may find themselves to be the sole person involved in vocational assessment. In such a case, they may wish to consider incorporating a vocational component in each evaluation conducted with an adolescent. Such a component could include measures of vocational interests, aptitudes, work habits, and career maturity, as well as traditional psychoeducational measures. There are many time and cost efficient instruments available to assess these traits, and school psychologists are referred to this chapter's annotated bibliography for references summarizing these instruments.

SUMMARY

Work is a integral aspect of human life. The extent to which one successfully adjusts to work influences physical and psychological well-being, and overall quality of life. It is important to ensure that students develop the skills they need in order to secure and maintain satisfying and productive work once they leave school.

As a result of nearly two decades of federal and state legislation, schools have come to assume a major responsibility for preparing their students for the world of work. Statistics indicate that the population with whom school psychologists most frequently work, students with disabilities, are at particularly high risk in respect to securing and maintaining satisfying and productive work once they leave school. Persons with disabilities are overrepresented among this country's underemployed and unemployed. The economic cost to society, and the personal costs to the disabled individual, of providing support for these unemployed persons is considerable.

Vocational assessment is designed to provide the information needed by school personnel to facilitate educational and vocational planning for their students, the goal of which is to allow the students to acquire the skills they need to make a successful transition to work and community life. This assessment involves a variety of school and community personnel and includes an evaluation of the students' psychological, educational/academic, physical/medical, vocational, and social functioning.

School psychologists have a critical role to play in the vocational assessment process. In particular, the school psychologist's psychometric expertise and knowledge of measurement theory can safeguard against the inappropriate selection and use of assessment devices in assessment programs, and against inappropriate interpretation and use of assessment data; their skills in assessment can be used to generate the data (e.g., in regard to intelligence, achievement, personality, social skills) that are necessary for effective vocational planning; and their knowledge of learning and behavior theory, and of adolescent psychology, can be used in the effective development and implementation of services.

ANNOTATED BIBLIOGRAPHY

Bolton, B. (1987). *Handbook of measurement and evaluation in rehabilitation* (2nd ed.). Baltimore, MD: Paul H. Brooks Co.
This edited text discussed vocational assessment from a rehabilitation perspective, provides reviews of various assessment instruments, and includes separate chapters on the vocational assessment of mentally retarded, deaf, and visually impaired persons.

Kapes, J. T., & Mastie, M. M. (1988). *A counselor's guide to career assessment instruments* (2nd ed.). Alexandria, VA: National Career Development Association.
This book summarizes uses and technical characteristics of frequently used vocational assessment instruments. Measures of interests, aptitudes, work values, and career maturity are included, as well as sections on test selection and instruments for use with persons with disabilities.

Levinson, E. M. (1993). *Transdisciplinary vocational assessment: Issues in school-based programs.* Brandon, VT: Clinical Psychology Publishing Co.
This book summarizes various theories of vocational development, discusses the advantages, disadvantages, and uses of different vocational assessment techniques, provides brief reviews of tests that can be used to assess different vocational assessment domains, and discusses the development of school vocational assessment programs from both a theoretical and a practical perspective. Six school vocational assessment program models are described, as are the roles of curriculum-based and community-referenced assessment in vocational planning. The book addresses the use of assessment data in vocational planning and includes sample forms that can be adapted for use in vocational assessment programs. A bibliography of references for professionals is also included.

Levinson, E. M. (1987). Children and career development. In A. Thomas & J. Grimes (Eds.), *Children's needs: Psychological perspectives.* Washington, DC: NASP.
This chapter summarizes the career development stages through which school-age children progress, identifies a career planning model that incorporates assessment as a means of gathering information necessary for effective decision making, and briefly discusses actions that can be taken by parents and professionals to facilitate vocational development among students.

Seligman, L. (1980). *Assessment in developmental career counseling.* Cranston, RI: Cranston Press.
This book discusses the career development needs of persons at different life stages and discusses the various assessment instruments and techniques that are appropriate for use at these different stages. Case studies provided for each life stage are discussed to illustrate the career development issues, assessment techniques, and counseling strategies applicable to each stage.

Best Practices in the Assessment of Adaptive Behavior

Patti L. Harrison
Bettina Robinson
University of Alabama

Adaptive behavior represents an extremely important component of every person's life. All people, regardless of age, gender, disability status, or other characteristics, must have a repertoire of day-to-day adaptive skills in order to function effectively and to meet the various demands of many environments and situations. Examples of adaptive skills used by most people on a daily basis include dressing, eating, and communicating and interacting with other people. Deficits in adaptive behavior can greatly impact on people's lives and can become major problems for children and youths.

Adaptive behavior assessment has been emphasized for many years in the definition of mental retardation, and professionals have called for the application of the construct of adaptive behavior to assessment and intervention for all students with disabilities (Harrison, 1990; Reschly, 1990). However, adaptive behavior assessment may not have reached its potential, and adaptive behavior scales may often be administered simply because they are "required." Recent changes in assessment practices in special education, with a de-emphasis of global test scores and of indirect measurement of underlying traits, have resulted in an increased emphasis on functional skills and on direct assessment of behavior (Elliott, 1991). The changes in assessment practices will hopefully result in a reconsideration of the purposes of adaptive behavior assessment and greater use of adaptive behavior assessment to design and monitor interventions for functional, adaptive skills.

The purpose of this chapter is to present adaptive behavior assessment as an important application of the problem-solving model of school psychology services, the theme of this book. The problem-solving model is particularly applicable for assessing adaptive skills, identifying deficits or problems in adaptive behavior, designing and implementing interventions for increasing adaptive behavior, and monitoring the effectiveness of adaptive behavior interventions. A problem-solving approach to adaptive behavior assessment will hopefully result in an abandonment of the use of adaptive behavior scales simply to meet requirements for special education placement and in the more appropriate use of adaptive behavior assessment that is tied to interventions.

OVERVIEW

The following elements form the foundations for using adaptive behavior assessment within a problem-solving framework: definition and characteristics of adaptive behavior, historical perspectives, and the current perspective of American Association on Mental Retardation ([AAMR], 1992).

Definition and Characteristics

Traditionally, adaptive behavior has been defined as personal independence and social responsibility, or the skills that are necessary to take care of oneself and get along with others (AAMR, 1992; Horn & Fuchs, 1987). The concept of adaptive behavior has been incorporated into broader models of *general competence* or personal competence, the Greenspan model of competence being the most widely utilized. According to one of the latest descriptions of the Greenspan model (Greenspan & Granfield, 1992), general competence consists of instrumental and social competence. Both instrumental and social competence have nonintellectual and intellectual aspects, as summarized below:

- Instrumental competence:
  - Intellectual aspects: processing and conceptual intelligence
  - Nonintellectual aspects: state and motor functioning
- Social competence:
  - Intellectual aspects: practical and social intelligence
  - Nonintellectual aspects: temperament and character

The intellectual aspects of social competence, practical and social intelligence, work together to develop adaptive behavior (AAMR, 1992). McGrew and Bruininks (1990) provided evidence to support the inclusion of adaptive behavior into a Greenspan global model of general competence.

Adaptive behavior is characterized by several elements, as summarized by Harrison (1990). Adaptive behavior is considered to be *developmental*, and adaptive skills increase in number and complexity as individuals grow older and encounter the demands of new environments and situations. Adaptive behavior comprises *several specific domains*, including self-help skills, interpersonal/socialization skills, physical and motor skills, communication, applied cognitive/academic skills, domestic skills, vocational/occupational skills, and responsibility. A person's adaptive skills are judged by the *expectations and standards of other people;* the other people include groups of people, such as communities, cultures, and ethnic groups, as well as specific persons of particular significance in a person's life, such as parents, teachers, and peers. Similarly, adaptive behavior is influenced by the demands of *specific situations and environments*, including home, school, community, and workplace. Finally, *ability and performance* are both important parts of adaptive behavior; a person's adaptive skills are considered to be deficient if he or she has the ability to perform a task but does not perform it as needed on a routine basis.

Historical Perspectives

The history of adaptive behavior assessment is closely tied to professional practice, legislation, and litigation in respect to serving the needs of persons with mental retardation (Harrison, 1990; Horn & Fuchs, 1987; Reschly, 1990). Prior to the early 1900s, definitions of mental retardation emphasized social competence, social norms, and adaptability to the environment. The development of intelligence tests in the early 1900s led to the widespread use of IQ scores to define mental retardation and a de-emphasis of adaptive behavior and social competence.

The practice of basing diagnosis and classification of mental retardation solely on scores from IQ tests was highly criticized. Throughout the mid 1900s professionals called for a return to consideration of adaptive behavior. The first official definition of mental retardation by the AAMR in 1959 indicated that deficits in adaptive behavior, in addition to low intelligence, must be substantiated for a diagnosis of mental retardation. Unfortunately, IQ test scores continued to be used as the sole criterion for mental retardation for many years.

Several significant events occurred in the 1960s and 1970s that impacted on the definition of mental retardation. A number of lawsuits across the country addressed problems in large, custodial facilities for persons with mental retardation. As a result, less restrictive, community programs were developed, and rehabilitation programs began to focus on identifying strengths and weaknesses in adaptive behavior and providing adaptive skills training that would allow individuals with mental retardation to function in the mainstream.

The practice of using only IQ scores to diagnose and classify mental retardation, concern about bias in IQ tests, and evidence of disproportionate numbers of students from minority groups in special education programs for mental retardation led to a number of lawsuits in the 1960s and 1970s. Although the overall decisions from lawsuits such as *Larry P. v. Riles* and *Marshall v. Georgia* differed, the conclusions about adaptive behavior assessment were consistent, and adaptive behavior was identified as an integral component of the classification of mental retardation. Education legislation, including the Education for all Handicapped Children Act in 1975 and the later Individuals with Disabilities Education Act in 1991, defined mental retardation in terms of both below-average intelligence and deficits in adaptive behavior.

Although the history of adaptive behavior assessment has been closely tied to diagnosis and classification of mental retardation, adaptive behavior assessment is also important for individuals with other disabilities (Reschly, 1990). Harrison (1990) summarized research supporting adaptive behavior deficits for individuals with learning disabilities, emotional disturbances, and sensory impairments and described the need for adaptive skills training for all individuals with disabilities. Historically, however, adaptive behavior assessment has been emphasized for diagnosis and classification of mental retardation and not for diagnosis and classification of other disabilities. In addition, adaptive behavior measures are typically used only for diagnosis and classification and are seldom used for planning interventions (AAMR, 1992).

Current Perspective: New AAMR Definition of Mental Retardation

The latest definition of mental retardation by the AAMR (1992) places greater emphasis on adaptive behavior than any previous definition for the following reasons: (a) IQ scores may have questionable validity in the diagnosis of mental retardation for an individual and diagnoses should show a more balanced consideration of IQ and adaptive behavior; and (b) assessment of adaptive skills provides confirmation of functional limitations of an individual and can promote linkage between functional limitations and an individual's need for services. The definition of mental retardation, according to AAMR, is as follows:

> Mental retardation refers to substantial limitations in present functioning. It is characterized by significantly subaverage intellectual functioning, existing

> concurrently with related limitations in two or more of the following applicable adaptive skill areas: communication, self-care, home living, social skills, community use, self-direction, health and safety, functional academics, leisure, and work. Mental retardation manifests before age 18. (AAMR, 1992, p. 5)

The AAMR definition is accompanied by four essential assumptions, two assumptions being directly related to adaptive skills. First, cultural, linguistic, communication, and behavioral factors must be considered for assessment of an individual to be valid. Second, adaptive skills limitations must be considered in the context of environments in the community that are typical of the age-peers of an individual and in relation to individualized needs and supports within the environments. Third, adaptive skills limitations may coexist with adaptive skills strengths or strengths in other areas. Fourth, the functioning of an individual with mental retardation is likely to improve if appropriate supports are provided.

As seen by the assumptions, a strong emphasis of the latest AAMR definition is identifying needs and planning and providing supports and services for individuals with mental retardation. Previous AAMR definitions identified four levels, or degrees of severity, of mental retardation: mild, moderate, severe, and profound. Instead of levels of mental retardation, the 1992 AAMR manual identifies four possible intensities of needed supports for individuals with mental retardation: intermittent, limited, extensive, and pervasive. Resources of supports for individuals may include personal supports, other people, technology, behavioral support, employee assistance, in-home living assistance, and community access.

BASIC CONSIDERATIONS IN ADAPTIVE BEHAVIOR ASSESSMENT

Adaptive Behavior Assessment Methods

A number of different methods can be used to assess adaptive behavior, including traditional, norm-referenced instruments and a number of important alternative methods.

Norm-referenced instruments. There are numerous standardized, norm-referenced adaptive behavior scales available for use. Brief descriptions of several instruments follow.

The *Vineland Adaptive Behavior Scales* (Sparrow, Balla, & Cicchetti, 1984a, 1984b, 1985) is composed of three forms. The Classroom Edition is a questionnaire designed for teachers to complete for children from the ages of 3 through 12 years. The Survey Form and the Expanded Form are in interview format administered to parents and guardians of infants and children through the age of 18 and to low functioning adults. In addition the Expanded Form contains a sequential guide for planning intervention programs and furnishes information about specific deficits.

The Vineland Adaptive Behavior Scales assesses four domains and 11 subdomains. The four domains include Communication, Daily Living Skills, Socialization, and Motor Skills. The domains are combined to provide an overall Adaptive Behavior Composite score. The Expanded Form and Survey Form contain a maladaptive behavior domain that is administered for children aged 5 years and older.

The *Scales of Independent Behavior* (Bruininks, Woodcock, Weatherman, & Hill, 1984) is designed for individuals from infancy through adulthood. The Scales of Independent Behavior require a highly structured interview with a third-party informant, such as parent or teacher, who is familiar with the child. The scale also may be administered to the examinee. The scale contains four adaptive behavior clusters: Motor Skills, Social Interaction and Communication Skill, Personal Living Skill, and Community Living Skills. The four clusters make up the Broad Independence Score. The Scales of Independent Behavior also include a Problem Behavior Scale that produces four maladaptive indexes.

The *Comprehensive Test of Adaptive Behavior* and Normative Adaptive Behavior Checklist (Adams, 1984a, 1984b, 1986) are scales intended for individuals from birth through 21 years of age. The Comprehensive Test of Adaptive Behavior assesses behavior by direct observation or through third-party informants when observation is not possible. The Normative Adaptive Behavior Checklist is composed of selected items from the Comprehensive Test of Adaptive Behavior and consists of a questionnaire completed by an informant, such as parent or teacher. Each instrument measures six areas: Language Concepts and Academic Skills, Sensory and Motor Skills, Self-Help Skills, Social Skills, Home Living Skills, and Independent Living Skills. The categories are combined to obtain a general adaptive score.

The *Adaptive Behavior Inventory* (Brown & Leigh, 1986) is a questionnaire designed for completion by teachers of individuals 5–18 years of age. The Adaptive Behavior Inventory assesses five categories of skills: self-care skills, communication skills, social skills, academic skills, and occupational skills. Scores in the five skill areas are combined to create the Adaptive Behavior Quotient.

The *Adaptive Behavior Scale–School Edition* (Lambert, 1981; Lambert & Windmiller, 1981) can be used to evaluate children aged 3–17 years. The scale is divided into two parts, Part 1 evaluating personal independence and Part 2 measuring problem behaviors. The Adaptive Behavior Scale–School Edition can be administered by two possible methods: conducting an interview with the informant or having an informant complete a questionnaire. The Adaptive Behavior Scale–School Edition contains 21 subdomains that are combined into scores for five categories: Personal Self-Sufficiency, Personal–Social Responsibility, Community Self-Sufficiency, Social Adjustment, and Personal Adjustment.

Alternative methods. The most traditional and widely used method of adaptive behavior assessment is to administer norm-referenced rating scales. Although norm-referenced instruments may provide useful information about adaptive behavior, these scales have a number of limitations. Many of the limitations are related to the reliance on ratings by third-party informants. The informants selected to complete the instruments may not be familiar with the all-inclusive environment of the subject or may present inaccurate information. For example, research suggests that teachers are often aware only of behavior in the school setting and have little knowledge about skills in the home or community (Harrison, 1985; Holman & Bruininks, 1985). Norm-referenced adaptive behavior scales usually focus on only the skills that can be assessed through a rating scale or questionnaire completed by an informant; the skills assessed by adaptive behavior scales may not adequately sample the many adaptive skills needed to function in a variety of environments. Norm-referenced adaptive behavior scales that utilize third-party informants may simply provide an assessment of the informant's *perceptions* of the subject's general adaptive behavior. Although informants' perceptions may represent important and useful information, they may provide very little information about specific adaptive skills.

Because of the inherent limitations of norm-referenced instruments, alternative methods of adaptive behavior assessment should be routinely used with norm-referenced scales to provide a more comprehensive adaptive behavior assessment. Methods that may be useful additions in comprehensive adaptive behavior assessment are informal interviews and observations, structured observations, sociometric techniques, and self-reports. Each of these four alternative methods of assessment should emphasize the identification of strengths and weaknesses in the major adaptive skill areas defined by the AAMR (1992). In addition, the alternative methods should be used systematically by all members of multidisciplinary teams to conduct ongoing monitoring and evaluation of improvements in students' adaptive behavior.

Informal interviews and observations can assist in answering a number of important questions about a person's adaptive skills and may help guide additional, more structured assessment. Informal interviews with significant others, such as parents and teachers, may assist in determining whether parenting and teaching styles or other environmental factors are potential reasons for children's adaptive behavior weaknesses (Harrison, 1991). Informal observations of subjects allow for assessing them in a variety of environments and suggesting possible avenues for additional analysis of behavior (Elliott & Gresham, 1987; Harrison, 1991). Norm-referenced adaptive behavior instruments depend a great deal on an informant's perception and memory, and informal observation allows an observer to view subjects first-hand and assess the validity of informants' responses to a norm-referenced instrument (Harrison, 1991).

Structured observations focus on direct and systematic observations of individuals in natural settings, such as the classroom, home, lunchroom, and workplace. According to Elliott and Gresham (1987), naturalistic observation is one of the most valid means of measuring a person's social skills. Shapiro and Skinner (1990) described two types of observational methods that can be applied to measuring adaptive behavior: the descriptive method and the quantitative method. The descriptive method requires observers to give narrative explanations of the adaptive behavior observed. Common collection techniques include daily logs, antecedent–behavior–consequent (A–B–C) evaluation, and narrative time sampling. The use of daily logs requires observers to record general, daily adaptive behavior; the reports generate an overall picture of behavior, including inconsistency and frequency of behavior. The second type of descriptive recording, the A–B–C method, provides more detailed information than daily logs concerning events that occur prior to the behavior and events that transpire following the behavior. Narrative time sampling requires observers to record the observance of adaptive skills at predetermined intervals and to provide a general description of overall behavior during the interval.

The second type of structured observation method, the quantitative method, allows observers to obtain countable data about specific behaviors. Quantitative procedures utilize the following techniques: event recording, duration recording, and time-sampling techniques. Event recording requires the observer to record the exact number of occurrences of a target adaptive behavior within a specific time frame. Duration recording is designed to measure the precise length, from beginning to end, of occurrences of an adaptive behavior. The final technique, time sampling, includes measurement of the number of times a behavior occurs during a specified amount of time, such as recording the presence or absence of a behavior every 15 seconds.

Sociometric techniques are frequently used to assess social acceptance of individuals by their contemporaries and can be useful in determining the impact of adaptive behavior deficits on the perceptions of peers. Sociometric assessment has two basic components, peer nominations and peer ratings, which may correspond to either behavioral or nonbehavioral standards (Gresham & Elliott, 1987). The standards for the peer nominations and ratings can focus on the adaptive skills of individuals. Behavioral criteria can be based on peers' perception of the specific adaptive behaviors demonstrated by individuals.

Nonbehavioral standards for sociometric techniques can focus on general activities or attributes or on the overall competence of individuals and not on specific adaptive behaviors.

A final alternative method is the use of *self-report* in measuring adaptive behavior. Self-report techniques rely on information obtained from interviews with individuals themselves, rather than relying on informants such as teachers and parents. According to Voelker et al. (1990), self-report measures have the advantage of obtaining firsthand information from the subjects themselves that otherwise might be unattainable from other informants.

Issues in Adaptive Behavior Assessment

A number of important issues relate to the assessment of adaptive behavior and use of adaptive behavior assessment in problem solving and decision making by school psychologists.

Psychometric issues. Although alternative assessment techniques are garnering attention and gaining in popularity, traditional, norm-referenced techniques remain the most widely used method of adaptive behavior assessment. The psychometric properties of norm-referenced adaptive behavior instruments must be carefully evaluated, and the psychometric limitations of norm-referenced instruments must be taken into account. Issues concerning norm samples, reliability, and validity have particular relevance for selecting the adaptive behavior instrument to be used and for interpreting the results of adaptive behavior scales (AAMR, 1992; Harrison, 1987; Kamphaus, 1987; Reschly, 1990).

Historically, many adaptive behavior instruments have been characterized by norm samples that may not serve as adequate comparison groups for many of the individuals with whom the scale is used. Some instruments were normed with a sample of individuals intended to represent the United States population, but the norm sample had a number of limitations (e.g., only specific regions of the country were represented; some socioeconomic status groups were underrepresented). Other adaptive behavior instruments were normed with samples of persons with disabilities but were represented only by individuals in specific settings (e.g., only residential settings; only school settings). When an adaptive behavior instrument is selected for use with an individual and the results are interpreted, the appropriateness of the norm group as a comparison for the person under evaluation must be considered. More recently, the norm samples for adaptive behavior instruments have improved, and many instruments have norm samples that can serve as adequate comparison groups for most individuals.

Reliability is another psychometric issue that must be considered when norm-referenced adaptive behavior scales are used. Although the global scores of many adaptive behavior scales may show evidence of adequate internal consistency reliability, many subtest scores have inadequate internal consistency. Subtest scores of adaptive behavior scales should be used with caution during interpretation of assessment results, and strengths and weaknesses suggested by subtests should be assessed more comprehensively with alternative methods of adaptive behavior assessment. Adaptive behavior scales, like most rating scales that rely on third-party informants, may be characterized by low stability and interrater reliability.

Validity of adaptive behavior scales has been investigated in a number of ways. Predictive validity research indicates that scores from adaptive behavior instruments exhibit low to moderate correlations with measures of school achievement, but higher correlations with criteria such as vocational placement, job performance, and other important "life achievement" criteria for individuals with mental retardation. The correlations between adaptive behavior and achievement instruments are expected to be relatively low, because the two types of instruments measure fairly distinct constructs. However, the low relationship between adaptive behavior and achievement scores and the higher relationship between intelligence and achievement scores could potentially contribute to the reliance on intelligence test scores in diagnosis of school-related problems.

A psychometric consideration of adaptive behavior assessment is factorial validity, or the number of dimensions found through factor analysis of the results of different adaptive behavior scales. Factor analysis has revealed inconsistent results concerning the number of dimensions measured by each scale (Harrison, 1987). Most adaptive behavior instruments claim a multidimensional perspective and offer scores for many dimensions. However, research has suggested that most adaptive behavior scales may measure only one dimension, a general factor that gauges personal independence (McGrew & Bruininks, 1989). The mixed results appear to be caused by differences in the theoretical frameworks that comprise each instrument and the factoring method that was employed (Harrison, 1987; McGrew & Bruininks, 1989). Practitioners should choose more than one instrument and several alternative, supplemental methods to obtain needed information, because of the lack of multidimensionality of a single adaptive behavior scale.

A final psychometric issue related to adaptive behavior instruments is treatment validity. Little research has been conducted that investigates the validity of using adaptive behavior scales in planning effective treatments, but research has supported the effectiveness of training adaptive skills (Bruininks, Thurlow, & Gilman, 1987; Holman & Bruininks, 1985). AAMR (1992) emphasizes the importance of determining needed supports for deficits in adaptive skill area and stresses the assumption that the life functioning of a person with mental retardation will improve if supports are provided for the adaptive skills areas. However, AAMR notes the need for development of adaptive measures that have programmatic implications.

Direct versus indirect assessment. Shapiro and Skinner (1990) described the continuum of indirect and direct assessment. The most direct form of assessment is observing behaviors of individuals in their natural environment. Movement along the continuum to indirect assessment results in assessment that does not take place in individuals' natural environment, that focuses on inferences about abilities and not direct observation of behavior, or that does not involve the actual participation of the individuals in their own assessment. Adaptive behavior can be assessed directly (for example, through structured observation) or indirectly (for example, through third-party ratings on a norm-referenced adaptive behavior scale). Both types of assessment should be utilized in a comprehensive adaptive behavior assessment, but each type has advantages and disadvantages. School psychologists must consider the strengths and limitations of each method when using adaptive behavior assessment during problem solving and decision making.

Although direct assessment relies on actual observation of another person and provides information not obtainable in using third-party informants, difficulties arise in accurate recording of behaviors. Problems that are often encountered in direct observation include timing errors, failure to provide enough accurate descriptive information, measurement of behaviors that occur infrequently, and subjectivity in reporting behaviors (Shapiro & Skinner, 1990). Direct assessment may also present a number of practical difficulties, such as the amount of time and training required for observers to assess behaviors in natural environments. However, as noted by AAMR (1992), direct assessment must be part of a comprehensive adaptive behavior assessment in order to evaluate subjects' skills and limitations, the strengths and limitations of the settings in which they are required to function, and the supports that they need within the settings.

Indirect measures of adaptive behavior, typically through interviews and norm-referenced questionnaires completed by parents, teachers, and staff members, offer general measures of adaptive behavior that can be obtained in a short amount of time. However, the use of indirect measures must take into account the limitations of informant-based instruments. Many studies have supported the low correlations between reports from different informants. For example, studies have found low correlations between parents' and teachers' ratings of a number of different behaviors, including adaptive skills, social skills, and problem behaviors (e.g., Gresham & Reschly, 1987; Harrison, 1989). Bracken and Barnett (1987) concluded that adaptive behavior scales have little convergent validity and interrater reliability. However, inconsistency between informants' ratings of behavior may simply reflect differences between informants' perceptions of the subjects or different expectations in the home, school, work, and other environments (Harrison, 1989). There is also evidence to support that self-reports of adaptive skills for older persons with mental retardation may provide useful information and may be similar to reports given by staff members (Voelker et al., 1990). Because of the concerns about informant ratings, it is recommended that indirect assessment of adaptive behavior routinely include two or more informants (AAMR, 1992; Reschly, 1990).

Decision making for special education eligibility. Several specific issues related to adaptive behavior assessment must be considered during special education decision making by multidisciplinary teams. The first issue is the continued, inappropriate emphasis on intelligence test scores in determining a classification of mental retardation, despite the inclusion of deficits in adaptive behavior, in addition to limitations in intellectual functioning, in legal and professional definitions of mental retardation. Reschly and Ward (1991) found that intelligence test scores continue to be used as the primary criterion in special education decision making about mental retardation. Multidisciplinary teams must use a more balanced consideration of intellectual levels, school achievement, and adaptive behavior during decision making about classification of mental retardation, and they must emphasize adaptive behavior strengths and weaknesses in intervention planning.

A question that often arises during decision making about classification of mental retardation is "What is a deficit in adaptive behavior?" Unlike guidelines for intelligence tests, few guidelines specify an operational definition of an adaptive behavior deficit or provide a cut score to indicate a limitation in adaptive behavior. AAMR (1992, p. 42) cautions against reliance on a precise cut score for operationalizing a deficit in adaptive behavior, for three reasons. First, AAMR recommends that information about a person's adaptive behavior must come from a number of sources and methods of assessment; the use of a single cut score would probably promote the use of only one norm-referenced instrument. Second, AAMR recognizes that individuals with mental retardation typically have strengths as well as weaknesses in adaptive behavior; the use of a single cut score would mask important intraindividual differences in adaptive functioning. Third, AAMR suggests that single cut scores provide little or information for planning treatments and interventions, and the focus of adaptive behavior assessment should include planning interventions and not just special education eligibility.

When adaptive behavior assessment is considered in addition to intelligence test scores during special education decision making about mental retardation, "declassification" may occur (Reschly, 1985). Declassification may result for students who would be given a classification of mental retardation if intelligence test scores were used alone, but who are found to have no adaptive behavior deficits and thus do not meet the criteria for the classification. Declassification may also result for students who have met the criteria for classification in the past, but who no longer meet the criteria because intervention has increased their adaptive skills. Multidisciplinary teams must carefully consider the potential effect of declassification on students and must include students' needs for intervention in addition to criteria for classification in determining eligibility for special education. In addition, teams must take into account AAMR's recommendation to focus on strengths and weaknesses in adaptive skills, rather than on a single cut score, when adaptive behavior assessment results are being considered for classification of mental retardation. Unfortunately, special education regulations for some states may have stringent criteria for adaptive behavior deficits in the classification of mental retardation. If so, declassification may occur even for students with special education needs.

Reschly (1982, 1990) described an important distinction for adaptive behavior of students in school: in-school adaptive behavior, which includes skills and behaviors necessary in a school environment, and out-of-school adaptive behavior, which includes skills and behavior necessary at home and in the community. Both in-school and out-of-school adaptive behavior should be addressed in special education decision making. Until recently, the distinction between in-school and out-of-school adaptive behavior has been rather blurred in special education decision making. For example, the Vineland Adaptive Behavior Scales has a version for parent informants and a version for teacher informants; both versions primarily measure out-of-school adaptive behavior, but the teacher's version is often used alone in determining special education eligibility. Teachers are asked to rate children's performance of a number of out-of-school adaptive behaviors about which they have little direct knowledge (Harrison, 1985). The new AAMR definition of adaptive behavior skills deficits, with its inclusion of in-school skills such as self-direction and functional academics and out-of-school skills such as self-care and home living, may be useful for planning comprehensive assessment of both in-school and out-of-school skills and for bringing both type of skills into consideration in determining special education eligibility.

Planning and monitoring interventions. An important feature of the AAMR (1992) manual is its emphasis on assessment and intervention for adaptive, functional skills and its problem-solving approach to providing educational services for students with mental retardation. AAMR prescribes that multidisciplinary assessment teams in schools must expand their assessment to include identification of supports and services that are consistent with adaptive skills needs. Furthermore, AAMR recommends that assessment must be ongoing and multifaceted, cannot be limited to norm-referenced assessment, and must be tied to devising and monitoring interventions.

Assessment for planning and monitoring interventions for adaptive skills can be viewed as a problem-solving sequence. AAMR (1992, pp. 116–119) suggests that one of the first steps should be to identify the functions that the student's assessment is to provide. AAMR provides several examples of assessment functions that may be included in an assessment plan: to determine priorities for adaptive skills needs to be addressed in an intervention plan, to plan transition to a vocational program, to assess progress toward meeting the objectives of the intervention plan, and to assess problem behaviors that may be interfering with attainment of skills.

Once the function of assessment have been determined, a broad assessment should be planned and conducted and assessment information should be analyzed. AAMR provides examples of a number of assessment methods that can be used to meet the assessment functions. For example, the priorities of an individualized educational plan (IEP) can be obtained with an ecological inventory, which may make use of structured interviews and norm-referenced adaptive behavior scales with informant services provided by parents, teachers, peers, or self-reports, as well as direct observation in home, school, work, and community settings. Assessment that is conducted to plan transition to a vocational program may include interviews and observations to determine the subject's current skills and the skills needed in the vocational setting.

AAMR then recommends that the assessment information should be translated into a description of needed supports to provide interventions for the student's limitations and weaknesses. The educational services and other needed supports should be planned and delivered. Finally, the student's progress is evaluated and modifications to supports and services should be made.

When planning interventions to provide the supports and services specified in the IEP, AAMR recommends that interventions be selected to provide widespread use of the skills to be developed within the student's environment, including home, school, leisure, and work setting. Interventions should strengthen the student's independence, community integration, and productivity. The techniques designed for the student should be age-specific and planned according to the student's strengths and limitations. Younger students with mental retardation may benefit from interventions that expose them to association with other children in the regular classroom and are more performance-oriented. Interventions that may be considered for younger students include the following: modeling, in which the student duplicates a task performed by another person; behavior rehearsal, in which the student practices a learned task over and over; and coaching procedures, which use direct verbal instruction with discussion of the desired behavior (Elliott, Sheridan, & Gresham, 1989).

Older students may benefit more from interventions that focus on job skills and independent living. Interventions for older students may include community-based instruction. McDonnell, Hardman, Hightower, Keifer-O'Donnell, and Drew (1993) found that community-based instruction is an effective technique for generalization of classroom-learned skills to natural settings. Other interventions that may be effective with older students include problem-solving training and self-motivational methods, such as self-instruction, self-management, and self-monitoring (Hughes, 1992; Lovett & Haring, 1989; Misra, 1992; Foss, Auty, & Irvin, 1989).

BEST PRACTICES IN ADAPTIVE BEHAVIOR ASSESSMENT

1. School psychologists should incorporate adaptive behavior assessment into a comprehensive problem-solving framework of conducting assessment and planning intervention. They should never conduct adaptive behavior assessment simply because it is "required" for a classification of mental retardation. They must view adaptive behavior assessment as an integral component of assessment of functional skills.

2. School psychologists should incorporate comprehensive adaptive behavior assessment into the assessment plan for *all* children experiencing learning and behavior problems, and not just children suspected of having mental retardation. Most children who are experiencing problems also have concurrent deficits in adaptive skills. Increases in adaptive skills represent important intervention goals for many children.

3. School psychologists should carefully plan adaptive behavior assessment to answer important questions about children's functioning and service needs. They should incorporate different methods of adaptive behavior assessment, including traditional, norm-referenced scales and alternative methods of assessment, in order to obtain ecologically valid information about children's functional strengths and limitations.

4. School psychologists may carefully select one or more norm-referenced scales for use in a comprehensive adaptive behavior assessment for a child. They should select scales based on consideration of the individual child's needs for assessment and the specific information provided by the scales. School psychologists should never make a practice of using the same adaptive scale for every child.

5. Norm-referenced adaptive behavior scales may have a number of practical and psychometric limitations. School psychologists should carefully evaluate norm-referenced scales before selecting them for use. Because no scale will overcome all limitations, school psychologists must carefully consider the limitations when evaluating and interpreting results.

6. School psychologists should always incorporate alternatives to norm-referenced scales into comprehensive adaptive behavior assessment. Methods such as informal interviews and observations, structured observations, sociometric techniques, and self-report by the client are necessary during adaptive behavior assessment in order to obtain more detailed information about strengths and weaknesses in a variety of settings and to plan and monitor interventions.

7. School psychologists should routinely include both direct assessment (e.g., informal observations, structured observations) and indirect assessment (e.g., informal interviews, self-reports, informant rating scales) so as to obtain a comprehensive ecological inventory of adaptive behavior. Although both direct and indirect assessment have strengths and limitations, the use of both allows assessment in multiple environment and with multiple sources of information.

8. School psychologists should encourage consideration of the following issues during decision-making for special education eligibility:

   a. Multidisciplinary teams must always use a balanced consideration of adaptive behavior, intellectual, and achievement assessment results when making decisions about a mental retardation classification. An emphasis on intelligence test scores, with an accompanying de-emphasis on adaptive behavior assessment, violates legal and professional guidelines and does not meet the needs of children.

   b. Multidisciplinary teams should not attempt to apply a single cut score on an adaptive behavior scale as part of the criteria for mental retardation. Although the use of a single cut score on an intelligence test is often used, such a practice should not be used with adaptive behavior assessment. Instead, multidisciplinary teams should emphasize multifaceted information from a number of sources and methods of assessment in order to identify strengths and weaknesses in adaptive skills.

c. "Declassification" may occur with individuals who have low scores on intelligence tests but no adaptive behavior deficits, especially if a multidisciplinary team emphasizes a single cut score on an adaptive behavior scale. Multidisciplinary teams should focus on children's needs for services during special education decision making, instead of just focusing on criteria for classification, and they should emphasize information about multiple adaptive skills, instead of just emphasizing a single, global cut score.

d. Multidisciplinary teams should consider both in-school and out-of-school adaptive behavior when making decisions. Students may have limitations in either or both areas, and either or both areas may pose needs for services for children.

9. School psychologists should never conduct adaptive behavior assessment solely for the purpose of classification of a disability. Adaptive behavior assessment should be conducted for planning and monitoring interventions. School psychologists should make careful and detailed plans in order to incorporate all important functions of assessment, conduct broad assessment to address the functions, and analyze assessment information to identify children's needs and provide supports and services.

SUMMARY

This chapter has described adaptive behavior assessment as a problem-solving activity for school psychologists. The current perspective provided by the AAMR (1992) provides a framework for assessing adaptive skills in order to gather information about an individual's functional limitations and needs for services. Comprehensive adaptive behavior assessment must include an ecological approach, in which norm-referenced and alternative methods and direct and indirect assessment are integrated. The adaptive skills of individuals across a number of settings and environments must be emphasized. Most importantly, the goal of adaptive behavior assessment should be to plan and monitor interventions for students. Adaptive behavior should never be conducted simply to provide a required assessment for a special education placement.

ANNOTATED BIBLIOGRAPHY

American Association on Mental Retardation. (1992). *Definitions, classifications, and systems of supports* (9th ed.). Washington, DC: Author.
The AAMR manual is an excellent resource concerning all important aspects of assessment, diagnosis, and intervention for individuals with mental retardation. The manual emphasizes new approaches in identifying support systems, multifaceted adaptive behavior assessment, and problem-solving techniques for providing services for individuals with mental retardation.

American Journal on Mental Retardation. (1992). Volume 96, special issue on "Social Competence."
The special issue of the leading journal in the field of mental retardation contains a variety of articles related to the social competence of individuals with mental retardation. Young children, adolescents, and adults are discussed in the articles, and topics include problem- solving strategies, self-perceptions, family roles, social skills, and new models of social competence.

Journal of Special Education. (1987). Volume 21, special issue on "Adaptive Behavior."
The series of articles contain a wealth of information pertaining to different aspects of adaptive behavior. The issue contains information about assessment, intervention, and adaptive behavior of individuals with different disabilities.

McGrew, K. S., & Bruininks, R. H. (1990). Defining adaptive and maladaptive behavior within a model of personal competence. *School Psychology Review, 19*, 53–73.
The article describes one of the few empirical studies investigating the theoretical aspects of adaptive behavior. The results of the study support a model of personal competence that includes adaptive behavior.

Reschly, D. J. (1990). Best practices in adaptive behavior. In A. Thomas & J. Grimes (Eds.), *Best practices in school psychology–II* (pp. 29–42). Washington, DC: National Association of School Psychologists.
This chapter should remain on school psychologists' reading lists for many, many years! The chapter is one of the best sources of information about adaptive behavior assessment owing to the outstanding discussion of key issues and the practical recommendations.

Best Practices in Intellectual Assessment

Daniel J. Reschly
Iowa State University

Jeffrey P. Grimes
Iowa Department of Education

School psychology was born in the prison of the IQ test. This controversial thesis was advanced by a prominent American psychologist in a commentary on school psychology two decades ago (Sarason, 1975). In this chapter, the appropriate role for intellectual assessment will be considered as school psychology emerges from this prison. Although our analysis will suggest a diminished role for intellectual assessment in the future, we recognize the necessity of best practices when intellectual assessments are conducted because these results typically are used in crucial decisions about children and youth.

INFLUENCES ON CURRENT PRACTICES

The dominance of intellectual assessment in current practice was apparent from the results of national surveys of school psychologists in 1986–87 and 1991–1992 (Reschly, Genshaft, & Binder, 1987; Reschly & Wilson, in press). In both surveys practitioners indicated that about two-thirds of their time was devoted to various aspects of special education eligibility determination. Intellectual assessment was nearly always a part of eligibility determination. The typical practitioner administered approximately 17 intellectual measures per month, most often one of the Wechsler scales. Intellectual assessment appears to be a virtual daily activity for school psychologists.

Historical Influences

The development of school psychology and special education are closely intertwined (Fagan, 1992). The earliest roots of school psychology were in a university-based clinic where psychological studies of children with learning problems were conducted. As school psychology developed from these early roots, services were provided most often by itinerant professionals in clinic-like settings; that is, children were brought to psychologists who studied them individually *outside* of the natural setting in which behaviors of concern occurred. This pattern of service continues today.

Standardized tests of intelligence and achievement were well suited to conducting analyses of learning problems in these clinic or clinic-like settings. Standardized procedures were used to obtain samples of behavior that became meaningful through comparisons to normative groups. These comparisons typically resulted in: (a) estimations of likely level of achievement; (b) identification of the cause(s) of low achievement; and (c) consideration of eligibility for a disability diagnosis (e.g., learning disability) and special education placement.

The measures were *indirect;* that is, they did not measure the actual behaviors of concern to the referral agent and the sample of behavior occurred outside of the natural setting. Direct samples of behavior in natural settings were not feasible due to the limitations in the availability of personnel and in the technology for obtaining reliable and valid direct behavioral samples. Although indirect samples of behavior were useful for many years and undoubtedly led to more appropriate educational services for many students, several disadvantages have become increasingly apparent over the past 10 years. The most important disadvantage is that the commonly used indirect measures are not closely related to interventions (see later section on reform themes).

Graduate Education

School psychology's history of using indirect measures in clinic or clinic-like settings was strongly established through graduate programs. In typical programs, the courses on administration, scoring, and interpretation of individual measures of cognitive functioning were emphasized more than courses on various intervention methods such as consultation, counseling, behavioral therapy, and behavioral assessment (Brown & Minke, 1986; Reschly & McMaster-Beyer, 1991). The nature of school psychology graduate education is changing, however, with many graduate programs now in various stages of initiating greater emphasis on assessment procedures that have direct connections to interventions.

Legal Regulations

Legal provisions in federal and state legislation and court cases are another significant source of influence on the use of intellectual assessment. The enactment of mandatory special education legislation at the state and federal levels in the 1970s had several influences including guaranteeing the access of persons with disabilities to educational services, thus expanding the numbers of students needing evaluations for possible diagnosis as disabled and subsequent special education placement. This legislation also established general standards for assessment practices that have had far reaching influences on intellectual assessment (Reschly, 1987).

Compliance with legal provisions is an ethical imperative; however, legal provisions are sometimes misinterpreted in ways that lead to rigid practices not in the best interests of children. For example, the critical federal regulation regarding the content of the multifactored assessment in initial placement or reevaluations states, "The child is assessed in all areas related to the suspected disability, including *if appropriate*, health, vision, hearing, social and emotional status, general intelligence, academic performance, communicative status, and motor abilities" (Individuals with Disabilities Education Act, 34 CFR 300.532; emphasis added).

The words "if appropriate" are crucial in this regulation. Professional judgment is needed in determining whether general intelligence information should be gathered regarding decisions to be made in individual cases. General intelligence information is not needed with many students referred for social-emotional or behavioral problems because (a) other information on cognitive functioning usually is available in school records and (b) IQ test results are unlikely to be directly related either to the emotional disturbance or behavior disorder diagnosis or to the development of interventions. Similarly, repeated administrations of IQ tests as part of triennial reevaluations, particularly for older students or students with severe disabilities, may be unnecessary because the results are not directly related to decisions that need to be made.

Legal regulations are not intended to eliminate professional judgment. The key federal regulation regarding the content of a multifactored assessment clearly requires that choices be made regarding which areas to include in initial eligibility determination and reevaluations. In a later section recommendations will be made that these choices be related closely to explicit questions established with the referral agent.

Disability Diagnostic Constructs

The conception and classification criteria in disability diagnostic constructs have enormous influences on the use of measures of intellectual functioning. Disability diagnostic constructs typically are formed by establishing critical dimensions of behavior and specifying criteria for decision making with individual cases. The traditional conceptions of mental retardation (MR) and specific learning disability (SLD) have used the dimension of intellectual functioning as a key component of the diagnostic construct. Classification criteria for MR and SLD in the special education rules of most states require that general intelligence be assessed as part of the eligibility determination evaluation. A substantial proportion of the use of intellectual assessment measures today occurs in the context of determining whether referred students meet the classification criteria for MR or SLD.

The conceptions and criteria related to diagnostic constructs change over time with the accumulation of research evidence as well as the development of different or expanded purposes of classification. Recent changes in the American Association on Mental Retardation classification scheme reflect somewhat less emphasis on general intelligence with more emphasis on adaptive skills and assessment of treatment needs (Luckasson et al., 1992). Other recent commentaries have suggested alternative ways to conceptualize and diagnose MR and SLD (Reschly, 1988a; Shinn, 1988; Siegel, 1989). These conceptions would place less emphasis on general intelligence and more emphasis on direct measures of student performance in natural settings. Implementation of these conceptions or other alternatives for conceptualizing traditional diagnostic constructs could markedly influence the use of intellectual assessment by school psychologists.

Reform Themes

Over the past five years increasing emphasis has been placed on the reform of school psychology through changes in the overall special education classification/placement system and in efforts to broaden services to low-achieving at-risk students. The capstone of the reform movement is less emphasis on eligibility determination and greater emphasis on the design and delivery of interventions to students within regular education settings (Graden, Zins, & Curtis, 1988; Reschly, 1988b). Significant changes are suggested in the roles of school psychologists and the kind of assessment information needed to address questions of interventions rather than questions of eligibility. Assessment in the new systems suggested will involve descriptions of problems in natural settings and information useful for designing, monitoring, and evaluating interventions. The kind of information useful for those purposes will necessarily involve curriculum-based measurement and behavioral assessment using techniques such as observation, direct measures of academic performance, ratings of social skills, direct and indirect measures of academic survival skills, and interviews with significant others such as teachers and parents.

As reform plans are implemented, we anticipate declining use of intellectual assessment. The current pattern of administering an intellectual assessment measure nearly every day by school psychologists will change with far greater emphasis given to more functional, that is more intervention-related, assessment procedures. However, intellectual assessment will continue, and that is as it should be. However, when intellectual assessment is used, it must be carried out in ways consistent with the theories and research on intellectual assessment and with well-recognized best practices. It is to these topics that the rest of the chapter is devoted.

BASIC CONSIDERATIONS

The voluminous literature pertaining to intellectual assessment cannot be reviewed in detail in this chapter. Thousands of journal articles, hundreds of book chapters, and scores of books have been written on topics related to intellectual assessment. This review, therefore, will cover only general findings that relate directly to best practices considerations. Readers are referred to other sources such as Sternberg (1982) and Sattler (1988/1992) for further information on theories, developmental patterns, research on various groups and tests, and reviews of measures.

Nature of Current Measures

The intellectual measures used most frequently in school psychology are composed of a variety of complex tasks ranging from items requiring simple memory to abstract problem solving. Most are atheoretical in the sense that the items and scales are not derived from applications of theories of cognitive development or information processing. Analysis of their psychometric structure typically yields a general factor, not unlike the concept of Spearman's "g," with one to three group factors (Vernon, 1979).

Although current measures such as the WISC-R and the Stanford-Binet Fourth Edition (SB) yield numerous scores, the most meaningful scores based on factor analytic investigations, as well as concurrent validity studies, are a composite of overall score and two or three scores reflecting group factors such as verbal comprehension and visual spatial problem solving. Scores on subtests, typically composed of similar items, are considerably less meaningful and substantial variation on the subtest scores is typical. The relationship of performance to important indices such as school achievement is typically best for the composite score and the primary or group factor scores. Relationships between important criteria and subtest scores tend to be highly variable and considerably weaker.

Meaning of Current Measures

Interpretation of the results of measures of intellectual functioning can be highly controversial. Perhaps the most widely accepted view is that measures of general intellectual functioning reflect the results of incidental learning through exposure to the general culture. The emphasis is on incidental learning because little if anything on the test is taught directly. However, schooling and the quality of educational experiences do influence intellectual development.

Academic performance. Intellectual measures are useful because of their relationship to other critical indices of human functioning. The most common use is to attempt to estimate likely level of performance in educational settings or to attempt to identify causes of poor school performance. This use of intellectual measures is supported by the well-known substantial correlation between intellectual functioning and school achievement. This relationship, ranging from a correlation of about .4 to .7 depending on the achievement criterion measure, reflects a substantial, but by no means perfect, association between intellectual functioning and school performance.

Occupational attainment. Intellectual measures are also correlated with occupational attainment. Although there is a broad range of ability associated with each occupational category, such as attorney or carpenter, there is a clear relationship with the average level of ability in occupational categories. Generally, the more prestigious the occupation the higher the average level of ability. This fundamental relationship rarely has direct applicability to school psychology decision making.

Cognitive processes. Performance on intellectual measures is also related to a variety of indices of cognitive processing. Campione, Brown, and Ferrara (1982) provided an excellent discussion of these relationships. Although their review focused primarily on studies of persons with mild mental retardation, the relationships they reported in the literature reviewed were interpreted as, for the most part, applying to all ranges of ability. According to Campione et al., performance on intellectual measures is positively related to the speed and efficiency of information processing, to the individual's knowledge base, to the spontaneous use of appropriate strategies in problem-solving tasks, to metacognitive operations whereby the individual exerts control over approaches to problem solving, and to the transfer of problem-solving skills to novel situations.

Perhaps the most salient result in the Campione et al. (1982) review was the interpretation of intellectual differences in terms of the capability of profiting

BEST COPY AVAILABLE

from incomplete instruction. In general, the higher the level of measured ability, the greater the individual's capability of learning through indirect or incomplete instruction. The latter bears strong relationships to the concept of incidental learning, cited earlier as the process through which much of the knowledge or problem-solving strategies on intellectual measures are learned.

It should be noted that the most widely used measures of intellectual functioning do not provide direct assessment of any of the cognitive processes. Rather, the complex types of items included on current measures require each of the cognitive processes to varying degrees. Furthermore, the scores on current measures, whether from subtests or from composite scales, cannot be interpreted directly, with few exceptions, as pure measures of any of the cognitive processes. Rather, these scores represent the products rather than the processes whereby individuals recall information, explain concepts, or solve problems.

Measured Intelligence versus Intelligent Behavior

The discrepancy between what is assessed on intellectual measures and effective, intelligent behavior has been recognized for many decades. In a 1921 symposium on the meaning of intelligence, E. L. Thorndike suggested three major facets of intelligence, social, mechanical (practical), and abstract thinking. He noted that the tests at that time, like most current measures, focused primarily on abstract thinking. A similar insight was offered by David Wechsler in his emphasis on intelligent behavior as the overall capacity to think rationally, act purposely, and deal effectively with the environment. Recently Sternberg (1985) has identified different components of intelligent behavior including social and practical intelligence (an aspect of which is tacit knowledge). All of these formulations recognize the distinction between what is measured on current measures and intelligent behavior. Intelligent behavior, if defined simply as the effectiveness in dealing with the environment, clearly involves a variety of intellectual and nonintellectual competencies. The IQ score from a well-standardized instrument such as one of the Wechsler scales represents some, but by no means all, of these competencies. It is critical for users of measures of general intellectual functioning to understand this distinction and to communicate the distinction to consumers of test results, that is, students, teachers, and parents. As Wechsler pointed out, a high level of measured intelligence, perhaps reflecting primarily abstract thinking, capabilities, is rendered quite useless in the absence of goal-directedness, motivation, persistence, or sufficient mental health stability to allow concentrated effort.

Variations in Performance: Intra-Individual Differences

Intellectual measures are designed to identify individual differences. Two perspectives can be used in examining these variations: Intra-individual differences involve variations within the individual over different tasks or items; inter-individual differences, between persons on the same tasks or items. Both types of differences have been used widely in intellectual assessment.

Intra-individual differences over subtests have often been used in making diagnostic decisions about individuals. For example, it was widely believed that larger subtest variations or unique patterns were typical of persons with various disabilities or neuropsychological deficits. It turns out that these assertions were and are still almost certain to be incorrect because a high degree of variation across item types or tasks is typical of normal persons. Kauffman (1976a, b) noted that large variations among the Wechsler subtests or in the verbal and performance scores were typical of persons in the standardization sample. Therefore, such variations could not be a defining or unique feature of any diagnosis that occurred infrequently in the general population.

Difference scores are nearly always less reliable than the separate scores on which the difference is based. This fact explains to a large degree why the intra-individual differences used in profile or scatter analysis are not useful bases for diagnoses or specification of treatment. If the reason for difference scores being less reliable is not immediately apparent, consider this analogy. If one is uncertain about when a vacation period begins and also uncertain about when the vacation ends, then, there must be even greater uncertainty about the length of the vacation. Similarly, if we are somewhat uncertain of the individual's Block Design score, also somewhat uncertain about the individual's Vocabulary score, then we are, by necessity, even less certain of the difference between the two scores.

Norms for subtest and scale differences are available for the most widely used tests (Sattler, 1988/1992). The norms often are organized around the size of the difference between two scores that is statistically significant at the .05 or .01 levels. These results are widely misunderstood. For example, on a Wechsler scale the Verbal-Performance Scale difference of about 10 points is statistically significant at the .01 level. Does this mean that only one per cent of the standardization sample obtained Verbal and Performance scores at that magnitude of difference? No! In fact, nearly 25% of persons in the standardization obtained Verbal and Performance scores that were different by 15 points or more. The statistical significance indicates the likelihood that a difference of that magnitude would occur by chance. The .01 or .05 levels indicate that the difference is likely to be real, not whether the difference is unusual or unique. It is essential to keep in mind that real differences in profiles of scores do occur frequently.

Developmental Changes

The performance of individuals also varies over time. IQ test results are relatively stable for many individuals after approximately age five to seven; however, the IQ scores for a significant percentage of individuals (at least 20%) change by 15 points or more between age 6 and maturity, and considerably larger changes of 30 to 40 points have been reported in a few cases. When large changes do occur, they tend to be associated with significant changes in the individual's environment or overall adjustment (McCall, Appelbaum, & Hogarty, 1973). The fact that IQ test results do change as a function of changes in the individual or the environment can be seen as evidence to support the most common interpretation of test results as reflecting *current* intellectual functioning. School psychologists need to be conscious of, and inform others about, the fact that scores do change and that inferences about future intellectual status of the individual are tentative.

Measures of Cognitive Processes

In recent years intellectual measures reflecting theoretical formulations of cognitive processes have begun to appear accompanied by suggestions that these measures replace some of the uses of traditional measures (Naglieri, Das, & Jarman, 1990). To date these measures have not been used frequently by psychologists although two distinct types have appeared. The Kaufman Assessment Battery for Children (K-ABC) is an example of a measure that attempts to assess cognitive processing for the purpose of improving learning through selecting an instructional method that capitalizes on processing strengths (Kaufman & Kaufman, 1983). In much the same fashion, attempts are made in neuropsychological assessment to match instructional method with "intact" neurological functions which are inferred from profiles of performance on various measures of cognitive and noncognitive behaviors (Reynolds, 1992). The major problem with these approaches is the absence of treatment validity (Kavale, 1990; Reschly & Gresham, 1989; Teeter, 1987, 1989). Although attractive, the idea of matching instructional method to cognitive or neuropsychological strengths has little empirical support.

A second use of cognitive process measures is represented by dynamic assessment procedures that attempt to identify strengths and weaknesses in the individual's problem-solving strategies. Attempts are then made to overcome deficits in strategies through direct cognitive modification (Lidz, 1987). Thus far, dynamic assessment and cognitive training have not had much impact on the practice of school psychology, in part because the dynamic assessment procedures have not been well standardized and the effectiveness of interventions related to improving cognitive processing are as yet unproved.

Inter-Individual Differences

The central purpose in most administrations of individual IQ tests is to determine how the individual performs in relation to a group of persons with similar characteristics. The standard scores and percentile ranks that give meaning to the performance and form the basis for the interpretation are based on the normative group. Obviously, the quality of the norms is crucial to the usefulness of the test. When we interpret the performance of individuals using the common scores such as IQs and percentile ranks, we are implicitly concluding that the normative group on which these scores were based constituted an appropriate comparison group for that individual. Careful consideration of that group's appropriateness is crucial to accurate interpretation of measures of intellectual performance.

Perhaps the most controversial finding related to intellectual assessment is that sociocultural groups differ in level and pattern of performance on measures of intellectual performance. These findings have appeared for many years (Kaufman & Doppelt, 1976; Lesser, Fifer, & Clark, 1965). The variations in level typically are confounded with group differences in socioeconomic status, rendering difficult interpretation of the source(s) of level and pattern differences. For that reason, extreme caution should be used in attributing causality to group differences as well as in interpreting the results of intellectual test performance for persons from groups that are culturally different. Mercer (1979) gives an excellent discussion of conditions that must be met before attributing intellectual test differences to hereditary causes. In fact, those criteria cannot be met for individuals, and estimations of their effects for groups are fraught with many possible sources of error. For these reasons, it is unwise to make inferences about causation in the everyday interpretations of inter-individual differences on measures of intellectual functioning.

Bias and Litigation

Allegations of bias are perhaps the most controversial issues related directly to the use of intellectual measures by school psychologists. Bias concerns are related to two populations: economically disadvantaged minority students and students with sensory or motor disabilities. Issues of possible bias need to be considered carefully when selecting intellectual assessment instruments, administering them, and interpreting the results.

Bias against minorities. Bias concerns are most often expressed regarding populations of minority students, particularly African-American, Latino, and Native American students. Considerable research was devoted to topics of bias in the 1970s and 1980s. The voluminous results generated from this research led to complex conclusions about intellectual assessment with minority students. First, there are multiple definitions of bias with varied meanings. The results of studies of bias depend heavily on the definition used. Definitions of bias include the following conceptions: (a) mean differences; (b) item bias; (c) psychometric characteristics of tests; (d) factor analysis of underlying test structure; (e) atmosphere or examiner/examinee interaction effects; (f) prediction; (b) selection ratios or disproportionate classification of students; and (h) social consequences, particularly use of test results to support racist interpretation of differences.

Most conventional tests, for example the WISC-R, are not biased according to the conventional definitions related to properties of items, psychometric characteristics, factor analysis, atmosphere effects, and prediction (Jensen, 1980; Reschly, 1979; Reynolds & Kaiser, 1990). Specifically, there is no evidence that conventional tests underpredict the actual performance of minority students. Conventional tests typically are found to be biased on the less well-accepted definitions such as mean differences, selection ratios/disproportionate classification, and social consequences.

The mean differences and disproportionate classification definitions, along with several conventional definitions, were key features of extremely costly and divisive litigation over the past twenty years. Four trials over these issues occurred in federal district courts between 1979 and 1986 (Reschly, Kicklighter, & McKee, 1988a, b). Three of the trials concluded that conventional measures of intellectual functioning were not biased, despite overrepresentation of minority students in special education programs, if certain crucial standards were met: (a) rigorous implementation of procedural safeguards in the referral, classification, and placement process; (b) implementation of a multifactored assessment designed to identify specific educational needs by a group of professionals; and (c) classification, placement, and programming decisions made by a team that included professionals and parents. The famous *Larry P* case in California resulted in a different decision on essentially the same facts (see Reschly et al., 1988a, b for an analysis of the cases and a discussion of implications for school psychology).

Bias against persons with sensory impairments. A slightly different concern about bias was reflected in the Federal Protection in Evaluation Procedures Provisions (IDEA, 34 CFR 300.530–534). This concern had to do with the use of measures that unfairly penalized students due to their sensory, motor, or language handicaps/differences. For example, the standard administration of the Wechsler verbal scale to a student with a hearing impairment or deafness likely measures the effect of the disability to a greater extent than the underlying construct of intellectual functioning. Similarly, use of highly verbal measures in the English language unduly penalizes students with mixed language capabilities (e.g., Spanish and English) or students with limited exposure to English. The population most frequently involved with the latter concern are of Hispanic origin, an increasing segment of the United States population and school psychologists' caseloads. Intellectual assessment of students with sensory or motor disabilities or language differences should, to the greatest extent possible, use administration procedures and response modes that do not merely reflect the effects of the disability or language difference. Use of special scales designed specifically for particular populations or non-language measures generally are preferred procedures.

Treatment Validity

The use of intellectual assessment is expected to decline because the results of intellectual measures are not related closely to treatment selection, planning, or evaluation. Witt and Gresham's evaluation of the treatment validity of the most widely used scale is a good metaphor for all such intellectual measures, "In short, the WISC-R lacks treatment validity in that its use does not enhance remedial interventions for children who show specific academic skill deficiencies . . . For a test to have treatment validity, it must lead to better treatments (i.e., better educational programs, teaching strategies, etc.)" (Witt & Gresham, 1985, p. 1717).

Of course, many respected school psychology professionals may disagree with the view of treatment validity stated here. Regrettably, space limitations do not permit a full representation of all views. It should be noted that the principal use of intellectual measures has been the classification of a child with disabilities leading to placement in special education. The reader may, therefore, wish to explore Kavale's (1990) analysis of the efficacy of special education programs organized around disability labels. From these results, as well as the negative findings on matching instruction to cognitive or neuropsychological strengths, many school psychologists have concluded that alternatives should be considered.

Alternative assessment procedures that focus on direct measures of behaviors in natural settings appear to be promising for use in classification decisions. Existing information confirms the value of these measures in intervention planing, implementation, monitoring, and evaluation. The move to alternative assessment procedures appears to provide better services to children and youth, as well as exciting and challenging opportunities for school psychologists to establish broader roles that utilize the full range of the psychological knowledge base.

Appropriate and Inappropriate Uses of Intellectual Assessment

Intellectual assessment may have a positive or negative impact on the individual depending on the context that leads to assessment and the outcomes of decisions made using intellectual assessment information. The importance of these context and outcome conditions was emphasized in a report of the National Research Council on equity in special education placement (Heller, Holtzman, & Messick, 1982). Consideration of alternatives to special education referral, classification, and placement — and, if these steps are necessary, focusing on the outcomes of classification and placement — moves the discussion of bias beyond arguments about test items and prediction equations (Reschly, 1979; Reschly et al., 1988b). Consideration of alternatives and outcomes is the central focus of system-reform efforts now underway.

Context. The typical context of intellectual assessment for school psychologists often involves determining eligibility for possible special education classification and placement. A two-pronged classification-placement process is established in federal and state special education legislation determining: (a) the need for special education, and (b) eligibility of classification. All too often the eligibility determination, rather than the need for special education, is addressed in the multifactored assessment that precedes classification and placement.

The least restrictive environment (LRE) principle from federal and state legislation places emphasis on attempts to resolve problems and to provide necessary services in regular education settings. Application of this principle implies that intellectual assessment and eligibility determination should not be the first choice in efforts to address learning or behavior problems.

The first phase of a system within which intellectual assessment can be used appropriately involves concerted efforts to resolve problems in regular education settings. This phase must include careful consideration of prior efforts to resolve the problem and systematic, high quality interventions. Typically, intervention quality at the prereferral stage is poor, lacking such essential features as behavioral definition of the problem, collection of baseline data, design of systematic interventions, and intervention implementation, monitoring, and evaluation. School psychologists have critical roles and essential contributions to ensuring the delivery of high-quality prereferral interventions.

Choice of measure and decision making. If the problem behavior is pervasive and persistent and beyond the purview of regular education, even with high-quality prereferral interventions, then consideration of special education eligibility is appropriate. At this stage, depending on state rules concerning classification of students as disabled, intellectual assessment may be part of the multifactored assessment. Intellectual assessment should not dominate the assessment process; rather, it should be one component of a comprehensive evaluation tailored to the referral problem and oriented to determining specific intervention need(s). Consideration of other aspects or dimensions of behavior should receive equal or more attention and decision making about eligibility and placement should reflect a clear balance between intellectual assessment and other important information.

The choice of intellectual assessment measure(s) must be based on the characteristics of the student. Student characteristics such as age, sensory status, language competencies, and acculturation are crucial factors that must be considered carefully when professionals select specific intellectual measures. For some students, few if any good choices exist due to various combinations of language differences, sensory impairments, and acculturation. In some of these cases, intellectual assessment should be avoided. In other cases, interpretations should be extremely cautious and decisions considered highly tentative.

The best measures available should be used when intellectual assessment results are part of significant decisions such as disability classification. Practitioners should base instrument choices on published critical reviews in authoritative sources such as the Buros Mental Measurement Yearbooks (also see Salvia & Ysseldyke, 1991) as well as their thorough study of the available technical and clinical information. Instruments that are short forms of more comprehensive measures, tests with a single-item type, and measures with dubious technical adequacy should be avoided.

Additional challenges arise when the effects of various disabilities such as sensory impairments or complex conditions such as autism or traumatic brain injury have to be considered in instrument choice and interpretation. Familiarity with a variety of instruments and knowledge of various disabling conditions is essential to choice of measures and interpretation of results in these complex cases.

Decision making. Information on intellectual functioning is used most often in decisions about classification of students as MR or SLD. Most students considered for these classifications will be performing near the margins of the classification criteria; that is, they will perform at levels where they are just eligible or just ineligible for classification. For example, an IQ less than 70 or 75 is used frequently as part of the criteria for a diagnosis of MR. The vast majority of the persons for whom an MR diagnostic decision is necessary will perform within a few points of the cut off score of 70 or 75. There are, for example, more students with IQs between 70 and 75 than have IQs below 70! A substantial proportion of cases will be within one standard error of measurement — often regarded as three to four points on the composite score of the most widely used instruments — of the cutoff established by the state rules.

The mechanical application of scores to classification criteria is inappropriate in MR and SLD eligibility decisions; rather, complex judgments are required. These complex judgments should reflect application of the convergent validity principle described by Gresham (1985), that is, the consistency of information over settings, sources, and data collection methods. Application of the convergent validity principle provides a means to integrate information from the multifactored assessment. For students performing near cut-off points, a pattern of information consistent with the underlying diagnostic construct should lead to classifying the child as disabled. On the other hand, one or more sources of information that are not consistent with the diagnostic construct should lead to not classifying the student as disabled.

Inappropriate or Questionable Uses of Intellectual Assessment

An array of inappropriate or questionable uses of measures of general intellectual functioning will be described briefly in this section. An obvious inappropriate use is to reach conclusions about the individual using only the results from a measure of intellectual functioning, without considering a wide variety of other information. It is not generally known how frequently this inappropriate use occurs, but it was of sufficient concern to merit a special sentence in federal regulations pertaining to assessment of students (IDEA, 34 CFR 300.532). We suspect that the results of an intellectual measure overshadow other important information quite frequently and that this other information, so valuable in developing interventions, is not used fully or is ignored.

Profile analysis. A frequent inappropriate use of a standard tool is to conduct a profile analysis for the purpose of differential diagnosis (e.g., determining whether the student is learning disabled or emotionally disturbed). As noted previously, a considerable degree of subtest score variation is typical. Differences between scales or subtests, because they occur frequently, simply cannot be a unique feature of any diagnostic category nor, therefore, the basis for distinguishing between diagnostic categories.

Group differences. Results from studies of groups of students also need to be interpreted cautiously with individuals. For example, the WISC-R ACID profile has been reported frequently in contrasts of learning disabled and normal achieving students (Sattler, 1988/1992). However, these findings are based on mean differences, developed from distributions of scores for normal achieving and learning disabled groups. The overall distributions overlap considerably. Therefore, a specific normal achieving child may obtain the ACID profile and a specific student accurately characterized as learning disabled may not obtain that profile. Therefore, conformance or nonconformance with the particular profile reported for groups is not an accurate indicator of the appropriate diagnosis for an individual child.

Personality or neuropsychological status. Profile analysis to determine neurological strengths or weaknesses or psychodynamic personality characteristics is also fraught with significant errors of logic and probably unreliable. These interpretations have a long history in applied areas of psychology including school and clinical. The empirical basis for the interpretations typically is weak or nonexistent. In virtually all instances, careful studies have not been done with individuals known to possess the underlying neurological or psychodynamic characteristics inferred from the test profile. Rather, analogical reasoning of the form, "what would this most likely mean," has been applied to analysis of the profile resulting in largely unsubstantiated inferences about the meaning of various subtests or scale discrepancies. These interpretations in the absence of empirical support are likely to be inaccurate, unreliable and, in any case, not related to effective intervention methodology or techniques (Reschly & Gresham, 1989).

Structured observations. One of the most frequent justifications for administering an IQ test to nearly all students with learning and/or behavioral problems is the opportunity provided for structured observations. The problem with this use is that the observations occur in an unnatural setting, on a one-to-one basis, with an adult who may have little continuing involvement, using tasks that do not reflect directly the difficulties that prompted the referral. Most important, the behavioral observations in the testing setting do not predict accurately behavior in other settings (Glutting, Oakland, & McDermott, 1989).

In contrast, structured observations in natural settings are enormously useful if gathered through use of direct measures of the behavior or concern and related to crucial environmental or instructional variables that can be used in interventions. The question is, in large part, whether we adapt to the client's setting or whether we require the client to adapt to our setting. Use of the IQ test for structured observations is also time consuming, usually requiring 3 to 4 hours for test administration, scoring, interpretation, and report preparation. Time is precious; the professional's time as well as the client's. Time devoted to

IQ testing inevitably reduces or eliminates the opportunity to conduct other assessment activities.

Inferences about group differences. The final inappropriate use relates to the use of results on measures of general intellectual functioning to support inferences about innate abilities of individuals or groups. Although these questions are investigated, sometime rigorously and sometimes not, the varied and controversial inferences from this research have little relationship to the day-to-day practice with diverse groups of students. The most popular conclusions from this research have varied throughout psychology's history and will likely continue to be modified as new information is generated and more sophisticated investigative techniques are developed and applied. Concern for accurate interpretation for individuals must include efforts to protect individuals from unwarranted inferences about innate abilities that may further diminish efforts to remediate problems and to intervene effectively.

Surgeon General's Warning

A kind of "Surgeon General's" warning can be formulated to protect children and youth from unwarranted inferences about their intellectual abilities and to remind all involved of the developmental nature of measured abilities (Reschly, 1979). This warning is far from perfect and concerned practitioners can develop appropriate modifications. However, the essential ideas are to protect students from inappropriate inferences such as the beliefs that (a) intellectual abilities are determined by genetic factors; (b) intellectual abilities are unitary; (c) IQ scores reflect all of intelligent behavior; and (d) performance on intellectual measures is fixed or unchanging. A statement such as the following should appear on test reports and be attached to test protocols if the latter are likely to be reviewed by other important parties such as teachers, other members of the multidisciplinary team, or parents.

> *IQ tests measure only a portion of the competencies involved with human intelligence. The IQ results are best seen as estimates of likely performance in school and reflections of the degree to which children have mastered the middle class cultural symbols and broad culturally rooted facts, concepts, and problem solving strategies. This information is useful but limited. IQ tests do not reflect innate genetic capacity and the scores are not fixed. Some persons do exhibit significant increases or decreases in their measured intellectual abilities.* (Reschly, 1979, p. 224)

BEST PRACTICES

Best practices considerations require careful judgments about (a) *when* and *how* intellectual assessment instruments are used; (b) the selection, administration, and interpretation of measures; and (c) prevention of misuses and misconceptions.

1. *Appropriate use requires a context that emphasizes prevention and early intervention rather than eligibility determination as the initial phase in services to students with learning and behavior problems.* The context within which the intellectual assessment occurs is crucial. The typical context is the investigation of the causes and correlates of learning problems. Special education eligibility may be a concern, but that concern should be investigated after, not before, the development, implementation, and evaluation of interventions within regular education settings.

2. *Intellectual assessment should be used when the results are directly relevant to well defined referral questions, and other available information does not address those questions.* Evaluations should be goal directed. The goal of the evaluation should be to address significant questions developed jointly between the psychologist and the referral agent. Some referral questions require consideration of current intellectual functioning, many do not.

3. *Mandatory use of intellectual measures for all referrals, multifactored evaluations, or reevaluations is not consistent with best practices.* It is not uncommon for all referred students to receive IQ tests, regardless of referral questions or behavioral problems. IQ test results simply are not relevant to many referral questions or reevaluation issues. A critical question is, "How would the intervention, classification decision, or selection of placement option change if an IQ test is or is not administered?"

4. *Intellectual assessment must be part of a multifactored approach, individualized to a child's characteristics and the referral problems.* The practice of using a standard battery, often dominated by IQ tests, for all children regardless of referral questions must be avoided. The standard battery typically involves an intellectual measure such as a Wechsler scale, a brief screening measure of achievement such as the Wide Range Achievement Test, and a brief measure of visual motor skills such as the Bender Visual Motor Gestalt. Standard batteries provide superficial information over very limited areas of functioning. In most instances, the standard battery does not relate directly to referral problems and is not well matched to characteristics of the child. Consideration and systematic assessment of other important areas of functioning using technically adequate measures is essential in order to develop a comprehensive perspective on the child and to address significant referral questions. The development of well refined referral questions should dictate the components of the comprehensive evaluation, rather than attempting to answer all questions through a limited set of instruments.

5. *Intellectual assessment procedures must be carefully matched to characteristics of children and youth.* A variety of instruments are available and no instrument is appropriate for all students. Special consideration needs to be devoted to choices of instruments with students exhibiting sensory or motor disabilities, language differences, or significant cultural differences. Basal and ceiling problems need to be considered. For example, a low functioning youngster close to the bottom age of the test norms will not be assessed adequately by the instrument because very few items will be administered due to ceiling rules.

6. *Score reporting and interpretation must reflect the known limitations of tests, including technical adequacy, measurement error, and general performance ranges.* Test scores should always be presented as ranges around an obtained score using confidence intervals. Furthermore, limitations in the norms for the test, in reliability or stability of scores, and questionable or undemonstrated validity, must be carefully considered and communicated to consumers of test information. Finally, the overall performance needs to be interpreted within broad categories, established by the test developer or established by other sources, for example, state special education rules.

7. *Interpretation of performance and decisions concerning classification must reflect consideration of overall strengths and weaknesses in intellectual performance and performance on other relevant dimensions of behavior, age, family characteristics, and cultural background.* Present behavior is described. Interpretations and descriptions of likely future performance are inferred from the sample of current behavior. The sample of current behavior may need to be regarded with varying degrees of tentativeness depending on age, family characteristics, and cultural background. Furthermore, overall pattern of strengths and weaknesses in intellectual performance as well as the individual's performance on other relevant dimensions such as adaptive behavior and social skills must be incorporated in interpretations and recommendations.

8. *Professionals should adopt strategies to prevent misuse and misconceptions about the results of intellectual measures.* Many consumers of test results including teachers and parents often view the findings as reflecting a predetermined characteristic and regard the results as fixed. Many do not see the distinction between the results of measures of intellectual measures and the much broader construct of intelligent behavior. A "Surgeon General's Warning" should appear on test protocols and reports as a means to reduce the likelihood of misuse and misconceptions (see previous section).

ANNOTATED BIBLIOGRAPHY

Aiken, L. R. (1987). *Assessment of intellectual functioning.* Boston: Allyn & Bacon.

Aiken provides an overview of intellectual assessment with interesting and useful information on patterns of intellectual abilities for various groups.

Kaufman, A. (1990). *Assessing adolescent and adult intelligence.* New York: Allyn and Bacon.

Kaufman provides an authoritative review of the research on adolescent and adult intellectual development and assessment.

Lidz, C. S. (Ed.). (1987). *Dynamic assessment: An interactional approach to evaluating learning potential.* New York: Guilford.

A well-organized overview of cognitive processing approaches to intellectual assessment is provided through chapters written by several leading figures.

Sattler, J. M. (1988/1992). *Assessment of children* (3rd ed., rev.). San Diego, CA: Jerome Sattler, Publisher.

Sattler provides an excellent text as well as an essential reference for individuals responsible for conducting intellectual assessments of children. Extensive information is provided on the most commonly used intellectual assessment measures with suggested guidelines for interpretation.

Sternberg, R. J. (Ed.). (1982). *Handbook of human intelligence.* Cambridge, England: Cambridge University Press.

Sternberg, R. J. (1985). *Beyond IQ: A triarchic theory of human intelligence.* Cambridge, England: Cambridge University Press.

The edited volume provides complex but extremely thorough treatments of essential topics related to human intelligence including chapters on attention, perception, learning, memory, reasoning, problem solving, personality, mental retardation, education, social policy, culture, genetics, development, and theories. Collectively, these chapters provide one of the best available treatments of the meaning of intelligence. Sternberg's paperback, *Beyond IQ,* provides an excellent treatment of his triarchic theory. Sections on social and practical intelligence and exceptional intelligence are especially useful in distinguishing between what current tests assess and the broader notion of intelligent behavior.

Best Practices Assessing Infants and Toddlers

Karleen K. Preator
Joseph R. McAllister
Children's Hospital of Pittsburgh
University of Pittsburgh

J. K. was born at 25 weeks gestation weighing 794 grams (1 lb. 12 oz.). He was the first baby born to his parents who had been married 9 years and he was the product of in vitro fertilization. J. K.'s parents were told that he had less than a 50% chance of surviving birth and the immediate neonatal period and, that if he did survive, he had a chance of having a range of disabilities from learning disabilities and hyperactivity to severe cerebral palsy and mental retardation.

J. K. survived delivery and was intubated in the delivery room. He had immature lung development and spent 30 days on a ventilator. Because of his prolonged oxygen requirement, he developed chronic lung disease and required supplemental oxygen through a tube in his nose for an additional 20 days. Head sonar revealed bleeding within the ventricles of his brain which resolved before discharge from the hospital. Other medical diagnoses during J. K.'s first 3 months of life included jaundice requiring phototherapy and anemia requiring blood transfusions. He passed his hearing screening. Ophthalmology screening revealed that he had immature retinas.

J. K. was discharged after 4 months of hospitalization. By then, J. K.'s parents were fluent in medical jargon and understood the multiple diagnoses as discussed by the neonatologists: hyaline membrane disease, bronchopulmonary dysplasia, bilateral grade III intraventricular hemorrhage, hyperbilirubinemia, and stage 3 retinopathy of prematurity.

At 16 months of age, only 2 months after discharge from the hospital, J. K. was referred to the school psychologist by his pediatrician for his first evaluation.

OVERVIEW

Changing and expanding roles provide school psychologists with ongoing challenges. With the implementation of Public Law 99-457, psychologists and educators throughout the United States are responsible for evaluating children from birth to 5 years of age for screening and diagnosis, eligibility for early intervention services, and program planning.

Emphasis on team assessment/intervention and family-centered decision making challenges traditional methods of the evaluation and eligibility process. Working with the medical community provides yet another challenge, and the children themselves present significant challenges: They do not answer questions, do not respond to instructions, are hard to motivate, and do not stay on task. Learning to interact comfortably with young children is an essential skill in mastering the art and the science of assessing infants and toddlers. Communication skills, in general, are also needed as the school psychologist may be called upon to serve as team coordinator.

Infant and toddler assessment involves an ecological approach to assessment and intervention and requires a broadened range of clinical skills. Instead of evaluation for eligibility purposes only, infant and toddler assessment is an ongoing process that begins the intervention process for the family during the first contact. Satisfaction with this first professional encounter may increase compliance with intervention recommendations and decrease the tendency to shop for alternative treatments (Parker & Zuckerman, 1990).

This chapter provides practicing school psychologists a resource to assist in the assessment of infants and toddlers. It is not a substitute for specialized training and the extensive experience needed for competence in this task, but rather an overview of infant/toddler assessment and an orientation to the literature to provide a base of best practices from which school psychologists can expand their existing knowledge and skills to include assessment and intervention of infants and very young children.

BASIC CONSIDERATIONS IN ASSESSING INFANTS AND TODDLERS

The first consideration in assessing infants and toddlers is the skill and training of the examiner. The goal of infant and toddler assessment is not to administer a test, but to gain a clear picture of the children's skills and limitations and a comprehensive understanding of family needs to facilitate intervention (Bailey & Simeonsson, 1988). Psychologists must be willing to observe and interact rather than test. The focus belongs on children's skills in the natural environment — what they do on a regular basis and what they can do given support and encouragement — not on the test.

Need for Psychologist Involvement

At present, the involvement of school psychologists in providing services to infants and toddlers is limited. Although the Individuals with Disabilities Education Act (IDEA) states that psychological services should be available to infants and toddlers, the role of school psychologists is not specified (McLinden & Prasse, 1991). Often it is educators, nurses, or other professionals who have the responsibility for assessment and program planning with this population, which bothers some school psychologists not at all. For them, infant/toddler assessment has as much appeal as changing a dirty diaper. Nor, historically, have school psychology training programs addressed the preschool population, leaving the average school psychologist ill-prepared to provide infant/toddler services (Epps & Jackson, 1991). However, the essential skills that make the school psychologist valuable in assessing school-aged children are no less critical in evaluating infants and toddlers. They include:

- Knowledge of psychometric methods and their limitations.
- Skills in working with parents.
- Observational skills.
- Understanding of typical and atypical development.
- Knowledge of current research and its application to intervention.

The generalist's background is insufficient for effective functioning as an infant/toddler school psychologist. Comprehensive training, including both specific academic preparation and extensive applied experience (Shonkoff & Meisels, 1991), is needed so that those assessing infants and toddlers acquire the requisite skills (see Figure 1). McLinden and Prasse (1991) suggest that "specialized preservice training is the best option" (p. 46) for developing expertise in infant/toddler school psychology. All this means that the postdegree individual moving into infant/toddler services faces formidable though not insurmountable challenges.

The traditional training and employment ground for school psychologists has been the school building. Other settings in which school psychologists are employed, however, include hospitals, neonatal intensive care units, outpatient diagnostic and treatment clinics, private practice, and mental health/mental retardation centers. Even within the confines of public or private schools, the role of the school psychologist is changing. With infants and toddlers, it is important to provide expanded services: assessment of development, behavior, and family resources; case management; coordination of interdisciplinary efforts; program planning; and evaluation of the effectiveness of intervention.

The well-prepared school psychologist can be an invaluable asset to the infant/toddler assessment team. No other discipline is likely to prepare its practitioners for the full range of responsibilities involved in infant/toddler assessment, particularly the job of discussing results with the family. As a profession, school psychology has two responsibilities regarding infant/toddler assessment: (a) ensuring that a sufficient number of competent individuals are prepared for the role, and (b) advocating for inclusion of school psychologists in assessment and intervention with infants and toddlers.

PUBLIC LAW 102–119

The 1986 amendments to the Education of the Handicapped Act, Public Law (PL) 99-457, have been called "the most important piece of federal legislation affecting special education since the passage of PL 94-142" (NASDE, 1986). PL 99-457 mandated availability of free, public, early intervention programs for children from birth to 3 years of age and a free, appropriate public education (FAPE) for children from 3 to 5 years of age. In 1991, PL 99-457 was combined with other legislation, passed as Public Law 102-119, and renamed the Individuals with Disabilities Education Act (or IDEA). Infants and toddlers experiencing developmental delays in one or more developmental domains are eligible for services under IDEA. These domains include expressive language, receptive language, fine motor, gross motor, cognitive, self-help, or socialization skills. In addition, children are eligible for early intervention services if they have a documented physical or mental condition which carries a high probability of resulting developmental delays. These conditions include genetic disorders such as Downs Syndrome, Williams Syndrome, Fragile X, tuberous sclerosis; inborn errors of metabolism such as Tay-Sachs disease; cerebral palsy or other neuromuscular disorders; medical diagnoses such as symptomatic congenital cytomegalovirus; or exposure to toxic substances such as in fetal alcohol exposure. At the state's discretion, children who are at risk medically or environmentally for substantial developmental delays if services are not provided may or may not be included as eligible for early intervention services. These children may be those raised by mothers with mental health problems, living in extreme poverty, homeless, or having medical conditions which place them at risk for developmental delays (e.g., prematu-

FIGURE 1. Skills required in infant/toddler assessment.

- Knowledge of the range of normal development.
- Ability to distinguish delays from aberrant development.
- Ability to write functional reports for families and early childhood educators.
- Familiarity with a variety of specialized instruments and techniques.
- Comfort with working in integrated, team format.
- Familiarity with early childhood curricula.
- Knowledge of related concerns such as medical issues.
- Expertise in working with families.

rity, asymptomatic congenital infection, chronic lung disease, or failure to thrive).

IDEA mandates a family focus to early intervention programming, stating that all early intervention services be guided by an Individual Family Service Plan (IFSP), developed jointly by service providers and families. The regulations for Part H (the Handicapped Infant and Toddler Program) of IDEA suggest a clear distinction between evaluation and assessment. *Evaluation* refers to the initial and periodic procedure to determine eligibility for early intervention or special education services. The term *assessment* is used to describe the ongoing process of monitoring a child's developmental progress, family strengths and needs, and the early intervention services required. Assessment occurs throughout the period during which early intervention services are provided (Campbell, 1991).

Eligibility for Programs Under IDEA

Most states require norm-referenced testing to determine eligibility for early intervention or special education services (Harbin, Gallagher, & Terry, 1991). Nevertheless, formal and standardized procedures are insufficient for understanding the child and must be supplemented. Infant assessment should employ "integrated strategies" (Campbell, 1991) as part of a covergent assessment program (Bagnato & Neisworth, 1991). Information is "gathered from several sources, instruments, settings, and occasions to produce the most valid appraisal of developmental status and to accomplish the related assessment purpose of identification, prescription, and progress evaluation" (Bagnato & Neisworth, 1991, p. 57). The result is richer and more informative data than a single score from a standardized test given under artificial conditions. At least one-half of the children evaluated for eligibility purposes and perhaps as many as 90% are declared "untestable" using traditional measures and standardized procedures (Bagnato & Neisworth, in press; 1991). Best practices in assessing young children demand expansion of our skills to include a combination of assessments — norm-based, ecologic, curriculum-based, judgment-based, and play-based — in addition to thorough parent interview and behavioral observation (Paget, 1990).

Bagnato and Neisworth (1991) provide comprehensive tables describing assessment batteries for specific developmental ages and handicapping conditions or disorders (pp. 245–251). These tables present examples of norm-referenced, curriculum-based, judgment-based, and eco-based assessment procedures such as the Bayley Scales of Infant Development, the Battelle Developmental Inventory, and the Hawaii Early Learning Profile.

Under IDEA, eligibility can often be determined on a *prima facie* basis. Genetic diagnoses and other medical conditions may have been identified prior to the initial evaluation and suffice in determining eligibility. Furthermore, many of the children referred for evaluation will function at a level or in a manner that precludes the use of standardized instruments. Thus the need for norm-referenced instruments to determine eligibility may be restricted to a relatively small percentage of the cases referred.

However, having already answered the eligibility question does not excuse the infant/toddler psychologist from the evaluation process. The evaluation serves other equally important functions including program planning, establishing a baseline against which future progress can be gauged, determining family needs and resources, and helping the family begin the acceptance and coping process. When there is a need to determine eligibility, the most appropriate course of action may be use of both norm-referenced and curriculum-based measures to address the multiple functions of the evaluation (i.e., "covergent assessment" or "integrated strategies").

BEST PRACTICES IN ASSESSMENT OF INFANTS AND TODDLERS

Best practices in infant/toddler assessment include:

- Understanding the referral.
- Specifying the purpose of the assessment.
- Effective collaboration with the medical community.
- Choosing assessment strategies.
- Interactive strategies.
- Working with families as team members.
- Assessment as an intervention.

Understanding the Referral

Children referred to school psychologists for evaluation and early intervention services in infancy or early childhood are likely to have less common conditions, more severe delays, or more severe disabilities than those referred at school age (Parker & Zuckerman, 1990).

Because of the nature of infant and toddler assessment, the referral for the initial evaluation may be parents' first experience discussing specific concerns and delays with a professional other than their physician. Parents may have wondered about their child's apparent delays and discussed them with their pediatrician or family physician, but the assessment process brings these concerns into focus. This experience can be frightening for families, especially if their worse fears are confirmed — fears that something is "wrong" with their child. In this respect, assessment and intervention begin simultaneously with the referral. "Intervention should begin with an assessment that informs and initiates the therapeutic process through its sensitivity to the parents' emotional state" (Parker & Zuckerman, 1990, p. 353).

> J. K.'s parents called the school psychologist at the request of the physician to schedule an evaluation. Although the next screening appointment had been scheduled for 6 months from that date, J. K.'s pediatrician was having concerns about his motor development and wanted him to be evaluated earlier. J. K. was now 8 months old and his parents were becoming much more comfortable with him. They expressed much less fear about the medical issues prevalent when he was in the hospital and immediately after his discharge and were able to enjoy playing and interacting with him as they would with a large, healthy, full-term baby. They occasionally expressed concerns to each other about waiting for the "next shoe to drop," knowing that, even though J. K. survived many significant problems during his neonatal period, he could still be affected by learning problems, cerebral palsy, or other developmental disabilities. The school psychologist arranged to visit J. K. at his home when both of his parents were able to be there. This required scheduling the appointment 3 weeks in advance to accommodate the busy work schedules of both J. K.'s parents and the psychologist. On the morning of the assessment, J. K.'s mother called to cancel the appointment — something had come up and they would be unavailable for the next 2 weeks.

Parent fears are often expressed in indirect ways: they may miss appointments, have difficulty identifying specific concerns, or report that "everything is fine."

Referrals may originate from physicians, preschools, day-care centers, or from parents themselves. Regardless, at an early stage of the assessment/intervention process, it is important to enlist support and help from parents whose concerns may be very different from those of the referring physician or day-care staff. If a child is referred for assessment because of motor delays but, according to the parents, cries constantly and is extremely irritable, the referral question is expanded by the dual concerns. Attending first to the parents' concerns about the irritability by providing suggestions and recommendations about behavior and calming may help enlist the support and trust of the parents. They may find it easier to listen to discussion about motor delays if they feel they have been heard when describing their own concerns. By listening to parent concerns first and intervening at that level, the school psychologist may find the parents more supportive and accepting of other concerns or questions.

> When J. K.'s rescheduled evaluation took place, the parents expressed concern about J. K.'s fussy period in the evenings and his poor sleep schedule. They reported that J. K. was inconsolable between 6 and 8 PM and would wake three or four times each night for a few sips from a bottle.
>
> A phone call to J. K.'s physician prior to the evaluation revealed concern about J. K.'s cognitive development. The doctor reported that J. K. was not yet cooperating with his parents in games of peek-a-boo. The physician noted that J. K. also stiffens his legs when he is picked up and would rather stand with his parent's support than sit.
>
> The school psychologist discussed with J. K.'s parents several ideas to console J. K. during his fussy period and was empathetic in discussing their frustrations and exhaustion after 4 months without a full night's sleep. The school psychologist also discussed the importance of the mother's and father's relationship and offered ideas that would allow them to go out for dinner and leave J. K. with his grandparents once a month.
>
> On the second visit, the psychologist was able to discuss concerns about cognitive and motor development with the assistance of an early intervention specialist and a physical therapist, providing suggestions to encourage J. K. to play and interact more consistently. The physical therapist cautioned against the use of a walker or other equipment that would make

J. K. want to straighten his legs. Early intervention services were also discussed as a possibility if J. K.'s development did not improve. A third visit was scheduled in 2 months.

Specifying the Purpose of Assessment

Assessment goals may range from developmental monitoring or screening of children in high risk categories to a complete diagnostic evaluation to reveal underlying causes of developmental delays, to determine eligibility for services, and to provide ongoing program planning and monitoring of program efficacy and child progress. Before launching into "testing," the school psychologist is responsible for determining the goals of the assessment in conjunction with the child's family and the referral source. Determining the assessment goals both aids the school psychologist in selecting assessment strategies and tools needed to provide the desired information and involves the parents as participants in the assessment/intervention process. Parents' hopes, fears, and unrealistic expectations can be addressed if their expectations for the evaluation process are discussed openly (Parker & Zuckerman, 1990).

Medical Considerations

Working with the medical community. An increasing number of low-birth-weight infants and children with medically complex conditions are surviving as a result of advancing medical technology (National Center for Clinical Infant Programs, 1985). Because these children are at increased risk for having special needs, psychologists should receive additional professional preparation concerning medical conditions. When families have questions concerning the development of their young children, they typically turn first to their family physician or pediatrician (McAllister, 1987). Therefore, many referrals originate from pediatricians or other physicians and many evaluation teams include medical input. Subsequently, it often falls to school psychologists to assume responsibility for integrating information from transdisciplinary team evaluations. They may also serve as a consultant for educational personnel working with children with medically complex conditions. It is imperative, therefore, that school psychologists receive training and experience with medical risk factors as well as behavioral characteristics associated with medical conditions, and that they feel comfortable communicating with health care professionals. This underscores the need for open and clear communication between schools and the medical community. Education and health care systems sometimes have difficulty interacting because of a different frame of reference and base of acquired knowledge (Morse, 1990) and a poor understanding of what can be reasonably provided by professionals in different fields (Marshall, Wuori, Hudler, & Cranston, 1987).

Why do physicians refer children for assessment/intervention? Some children are referred because parents have expressed concerns about delayed developmental milestones. Some are referred for developmental monitoring because of significant risk factors. Often, developmental screening and observation suggests developmental problems. Because of the physician's focus on health care, developmental screening is only one (albeit a very important one) component of health care. Physicians must rely on the expertise of psychologists and educators to identify specific needs and strengths of a particular child (see Figure 2). They may have questions about appropriate intervention strategies, behavior management strategies, or early intervention programs available to a family.

The importance of communicating with a child's physician cannot be over-emphasized. It may be the responsibility of the school psychologist and educational staff to make the first contact with the physician to meet a child's and family's developmental, medical, and educational needs. Some physicians who are with patients much of the day prefer to be interrupted when a professional phone call concerning a patient is announced; some prefer that the professional leave a detailed message. Informing the physician's receptionist of the child's name, the purpose of the call, and the psychologist's available hours will allow the physician to be prepared with the child's chart in hand for the return call. Physicians often appreciate hearing about psychologists' concerns, observations, and recommendations following assessment/intervention.

Prematurity. When evaluating development during the first 2 years of life, researchers and clinicians often think of premature infants in terms of their due dates or age post-conception rather than their actual birth dates or chronologic age. For example, a baby who is 6 months old but was born 3 months early has an "adjusted age" of 3 months. When comparing developmental milestones and skills with other children, this infant should be compared with other 3-month-old children instead of with 6-month-old age mates. The infant brain continues to develop at a rapid rate during the neonatal period (Gould, 1977). An enormous amount of energy is spent on growth and development, fighting infection, and adapting to a neonatal nursery with its frequent alarms, buzzers, urgent voices, crying babies, and glaring 24-hour lighting. Children who have been very ill during the neonatal period may lag behind even their adjusted ages (Harrison, 1983).

J. K.'s first evaluation took place when he was 6-months old — according to his actual birth date. Because he was born nearly 4 months early and spent his first 4 months of life in the Neonatal Intensive Care Unit, we would expect him to demonstrate developmental skills at approximately a 2-month level.

FIGURE 2. Services school psychologists can provide to child's physician following assessment.

- Explain educational services available in the community, mandated procedures, the roles of educational personnel, and ways teachers and school psychologists can help monitor a child's developmental progress and physical well-being.
- Send a letter that can be kept in a child's chart concerning evaluation findings and recommendations made following referral for assessment/intervention. Highlight medical needs and questions. Do not send more detailed documents, such as IEPs and IFSPs unless specifically requested.
- Alert physician to suspected medical conditions by providing symptoms, characteristics, or observations that bring a specific medical disorder to mind.

Although J. K.'s chronologic age is 6 months, his "adjusted" or "corrected" age is 2 months.

Although, in many respects, the development of infants born prematurely is similar to that of infants born at term, there are some significant differences. In general, the motor skill development of premature babies tends to lag behind other skills. Shoulders may be retracted and premature infants may keep their arms and hands pulled back in line with or behind their shoulders rather than relaxed at the midline. Increased muscle tone may be seen, especially in the first year (Harrison, 1983). In the case of these developmental differences, assessment must focus on the child's functional skills: Do increased tone and shoulder retractions interfere with functional movements? Can the infant bring hands to midline to grasp a cookie or an attractive toy placed in front? Are stiff legs interfering with the infant's ability to roll or sit comfortably?

Most premature infants do not have lasting medical or developmental problems. However, very low birthweight babies (|3\\i|||1 1500 grams/approximately 3 lbs. 5 oz.) and babies who have experienced severe perinatal complications may develop significant handicapping conditions. These conditions may include sensory impairments, cerebral palsy, or mental retardation (Harrison, 1983) or more subtle learning problems such as learning disabilities, attention deficit hyperactivity disorder, or other academic problems (Sameroff & Chandler, 1975). Although it is impossible to predict a newborn child's future development, the prevalence of significant physical, mental, or sensory impairment increases as birthweight and gestational age decrease (Harrison, 1983). The addition of significant medical complications may also increase the likelihood of future developmental problems.

Babies born prematurely have several medical needs and complications (Figure 3), some of which are more common or more serious than others. School psychologists working with infants and toddlers should be aware of these medical problems. Although there are many other medical problems frequently associated with prematurity, school psychologists should pay close attention to neurologic information (presence of intraventricular hemorrhages or cysts, history of seizure, evidence of sensory impairment) and the level of lung disease in children. Grade IV intraventricular hemorrhages are often associated with neuromotor disorders such as cerebral palsy; severe chronic lung disease and prolonged requirements for supplemental oxygen may result in more diffuse brain dysfunction and mental retardation or specific learning disabilities.

Medical diagnoses. School psychologists must make an effort to learn about the developmental and behavioral implications of a syndrome, medical condition, or risk factor before observing the child or interacting with the family. This information can be obtained from the child's physician or school nurse. It is important to know whether the condition is static or degenerative, understand the effects of medications on the child's state control, and know whether the child requires special handling because of a medical condition. It is also important to know the limits of a medical diagnosis as an indicator of future functioning levels. For example, a child with a diagnosis of Apert Syndrome may have substantial physical malformations and require extensive physical and occupational therapy services but may have normal intelligence.

Working with Families as Team Members

IDEA requires that families be an integral part of the evaluation and intervention process. The infant/toddler psychologist should strive to include the family in all aspects of the evaluation, including:

1. Using the family as a source of information about the child.

2. Determining family needs and resources for the IFSP.

3. Including the family in direct assessment.

4. Developing program recommendations which fit with family priorities for services.

FIGURE 3. Terms associated with premature infants.

- **Apnea** — lack of breathing for longer than 15 or 20 seconds.
- **Bradycardia** — Slower than normal heartbeat.
- **Hyaline membrane disease or respiratory distress syndrome** — Immature lungs. Some premature babies lack sufficient amounts of surfactant, the substance that keeps the lungs' air sacs from collapsing, causing difficulty with breathing. Many premature infants require intubation and mechanical ventilation after birth: A tube is inserted into the trachea and oxygen is pumped into the lungs.
- **Bronchopulmonary dysplasia** — Mechanical ventilation and supplemental oxygen delivered to immature lungs can produce damage to the lungs over an extended period of time. This condition is called BPD, a form of chronic lung disease.
- **Intraventricular hemorrhage** — Brain bleeds. Tiny blood vessels in the brain have fragile walls in premature babies. These blood vessels may burst with fluctuations in the baby's blood pressure and bleeding can occur into the ventricles. These bleeds are graded by severity: Grade I is the least severe indicating that bleeding is limited to a small area within the ventricle to grade IV in which blood fills the ventricles and may be associated with bleeding in the brain tissue.
- **Retinopathy of prematurity** (formerly called retrolental fibroplasia) — Abnormal blood vessels in immature retina. In its most severe stage, it is associated with detached or detaching retinas. Treatment may include cyro surgery to stop the tearing.

Note. Adapted from *The Premature Baby Book: A Parents' Guide to Coping and Caring in the First Years* by H. Harrigan, 1983. New York: St. Martin's Press. Copyright © 1983 by St. Martin's Press.

5. Presenting findings and recommendations to parents in a therapeutic manner to facilitate the process of acceptance and coping.

Information source. Parents can provide an additional source of information about the child to partially obviate the limitations of direct assessment and observation. Specifically, there is an increased risk that the sample of behavior seen in direct assessment is not representative due to fatigue, wariness, or a host of other factors, hence the need for cultivating "multiple sources" of information in assessing infants and toddlers (Bagnato & Neisworth, 1991). Some instruments, such as the Battelle (Newborg, Stock, Wnek, Guidubaldi, & Svinicki, 1988) have been structured to permit any combination of direct assessment, observation, and parent report when scoring items, thus allowing the school psychologist to include information not available through direct assessment. Many parent report measures are also available for quantifying parental perceptions such as the Assessment, Evaluation, and Programming System for Infants and Children (Bricker, 1993) and the MacArthur Communicative Development Inventory (Fenson et al., 1991). While some have suggested that parents tend to have inflated estimates of their child's abilities (e.g., Rogers, Booth, Duffy, & Hassan, 1992), others have found parents to be reliable reporters of their children's developmental level (Bricker, Squires, Kaminski, & Mounts, 1988), perhaps even more accurate than professionals (Gradel, Thompson, & Sheehan, 1981). In part, the accuracy of parents may be a function of how the information is elicited. Parent report measures that tap current, observable behavior and do not require interpretation generally provide the most reliable results (Lichtenstein & Ireton, 1984). Thus, the supposed lack of parental objectivity may in fact be "the result of the professional's lack of clarity and specificity in the questions asked" (Lichtenstein & Ireton, 1984, p. 87). Similarly, Bailey and Wolery (1989) have noted the "high level of skill required both to formulate appropriate interview questions that will evoke specific assessment data and to support qualitative, non-judgmental interpersonal relationships" (p. 257).

Individual family service plan. Because of the importance placed on the family as the focus of infant/toddler special education services, each child must have an Individual Family Service Plan (IFSP). Like the Individualized Education Plan (IEP), the IFSP specifies current levels, necessary services, duration of services, and methods for evaluation. The IFSP differs from the IEP in that it includes a statement of the family's strength and needs as they relate to the child's developmental needs. Furthermore, the IFSP must address both child and family outcomes anticipated as a result of the intervention. The IFSP is intended to be the instrument for enabling and empowering families (McGonigel, Kaufman, & Johnson, 1991). It provides the structure in which information is integrated, including family priorities. It is not intended to be intrusive; the family can freely decline or limit family assessment.

BEST COPY AVAILABLE

A number of instruments are available for family assessment (e.g., the Family Needs Scale in Dunst, Cooper, Weeldreyer, Snyder, & Chase, 1988). However, informal discussions with families may be the most appropriate and efficient way of determining needs and strengths (Beckman & Bristol, 1991) and are required according to IDEA regulations.

Inclusion in assessment. Parents' direct participation in the evaluation program has many payoffs. Developing rapport with the parent sets the stage for family-focused intervention. Family involvement serves to make them participants in the first stage of the intervention process, increasing the likelihood that they will find the team's conclusions and recommendations acceptable. Parents can be asked to attempt evaluation tasks with the child; this may elicit the child's best performance by increasing his or her comfort level and compliance (Parker & Zuckerman, 1990). The course of the evaluation also provides frequent opportunities for the psychologist to demonstrate optimal approaches for working with the child. Modeling approaches to interaction with an infant with disabilities can improve parent behavior more than verbal instruction alone (Minor, Minor, & Williams, 1983). Active parent involvement (as opposed to passive observing) can enhance the quality of parent–infant interactions (Parker & Zuckerman, 1990).

Program recommendations. Family life situations and family needs must be a focus of early intervention program recommendations. Many families of children who are eligible for early intervention services will have clear ideas about the most appropriate educational alternatives for their children. Program planning and IFSP development should meet child educational goals while taking into account family life situations for educational placement. For example, if a family is expecting a new baby, home-based services may be more appropriate for the first year; if family priorities include increasing peer interactions, toddler play groups in which parents are actively involved may be the best program alternative.

Feedback. Parker and Zuckerman (1990) note that the distinction between assessment and intervention is relatively arbitrary, and, in fact, intervention begins with the assessment. In discussing the results of the evaluation with the family, the infant/toddler psychologist is often the first professional to raise sensitive issues about developmental status, needs, and (to the extent feasible and appropriate) prognosis. Perhaps the most difficult and challenging task for the infant/toddler psychologist is the initial discussion of a disabling condition with the family. Many parents express frustration and anger regarding their initial contacts with professionals (Teglasi, 1985). This conflict may stem partially from a gap between what parents expect and what a professional can legitimately provide. Parents often come seeking "answers," wanting to know the reason for the disability and what can be expected. Yet, except in cases of profound disabilities and some genetic disorders, it is seldom appropriate for a definitive diagnosis at the infant/toddler stage, thus uncertainty and ambiguity are prevalent (Calnan, 1984). This gap between what the parents expect and what professionals are able to provide may leave the parents unsatisfied and delay the process of acceptance and coping. Recently, various factors have been identified that can decrease parental dissatisfaction with the process (see Figure 4; Krahn, Hallum, & Kime, 1993).

Regardless of how sensitively the psychologist presents information, an additional session may be needed to present additional and more detailed information because parents may not "hear" anything after discussion of diagnosis (Parker & Zuckerman, 1990). The process of accepting that one has a child with disabilities has been compared to the stages passed through in dealing with death: denial, anger, bargaining, depression, and acceptance (Kubler-Ross, 1969; Murray, 1985). Professionals should not attempt to "work through" the entire acceptance process with parents in the course of a single discussion. Generally, the process will take years and significant life events (such as moving from a toddler to a preschool program) may cause previously resolved issues to resurface (Harris & Powers, 1984).

The professional confronted with the denying or angry parent may feel frustrated by the parent's failure to accept the "obvious." The temptation may be to convince the parent of the severity of the child's deficits. But the tenacity with which parents cling to an idealized concept of their child suggests that the phases of acceptance may serve an adaptive purpose (McAllister & Vanden Heuvel, 1989). At least initially, there may be a relationship between acceptance of the disability and acceptance of the child. Too rapid a shift toward acceptance of the disability may change the nature of the parent–child relationship. Rather than "pushing" the parents into acceptance, a more appropriate professional role may be to help parents achieve a balance between maintaining hope for their child's future and coping with the child's current status. Providing the parents with direction and with functional roles in the intervention process may also facilitate the coping process.

Choosing an Assessment Strategy

Staging an assessment is much more difficult for infants and toddlers than for school-aged children. To ensure optimal child performance, the school psychologist must be a master at arranging the environment, selecting materials, and adjusting language and style to sustain the child's attention (Bagnato & Neisworth, 1991). For children with mild disabilities, the testing environment is an important factor. Factors

FIGURE 4. Providing feedback to parents.

- Both parents and/or other supporting family members should be present, if possible.
- The infant should be present.
- The psychologist should show acceptance of the infant as a person through physical contact and statements regarding the child's strengths and positive characteristics.
- Jargon, including relatively common professional terms, should be avoided.
- The limits of prognostication and the range of possible outcomes should be explained.
- The family should have as much time as needed to ask questions.
- Parents should be provided with the opportunity to express their feelings but not be required to do so.
- Additional sources of information should be provided.
- The oportunity to contact other parents should be facilitated.
- A follow-up session should be offered.
- The family should be provided with private time at the conclusion of the discussion.

that can help elicit ecologically valid information for diagnosis and prescription include:

- A friendly and familiar setting with minimal distractions.
- A small table and chair in which a child can sit with feet on the floor for toddlers or a mat or large blanket for infants.
- The presence of parents to reassure the child.

For children with severe disabilities, adequate seating or body positioning and a variety of multisensory, response-contingent toys as well as sensitivity to the child's strengths may mean the difference between a description of the child's needs and a statement that the child is "untestable."

Staging an assessment for children from birth to three is based on multiples: multiple purposes, multiple measures, multiple sources, multiple settings, and multiple occasions (Bagnato & Neisworth, 1991).

Multiple purposes. Multiple purposes of infant/toddler assessments include confirmation of a developmental problem, description of functioning levels in developmental domains, diagnosis of a developmental disability such as autism or cerebral palsy, and facilitation of appropriate intervention strategies. These goals are not mutually exclusive and diagnosis and prescription should be addressed simultaneously throughout the assessment/intervention process (Teti & Gibbs, 1990).

Multiple measures. To provide diagnostic and prescriptive information based on an accurate assessment of a child's strengths and limitations, a covergent assessment approach is imperative. Norm-referenced tests for infants and toddlers have been criticized on numerous grounds including:

- Limited utility in program planning and evaluation (Bagnato & Neisworth, 1991).
- Lack of theoretical underpinnings, insensitivity (Cicchetti & Wagner, 1990).
- An overly narrow, unitary construct of development (Cicchetti & Wagner, 1990).
- Lack of adaptation for individuals with various disabilities.
- Exclusion of individuals with disabilities from the norming group (McCune, Kalmanson, Fleck, Glazewski, & Sillari, 1990).
- Developmentally inappropriate expectations for performance "on demand" (Zelazo, 1982).

However, the ability of a test to discriminate children with disabilities from nondisabled children may be more important than the stability of scores over time for the entire population (Ross, 1989). The Bailey Scales of Infant Development and the Mullen Scales of Early Learning are among those norm-referenced instruments that satisfy this criterion (e.g., Maisto & German, 1986).

Play-based assessment and curriculum-based assessment are more useful for identifying instructional strategies and educational goals (Bagnato & Neisworth, 1991; Campbell, 1991). Curriculum-based assessments are also useful for monitoring child progress and the impact of early intervention or special education services on a child's developmental skills. Judgment-based scales allow parents and professionals to quantify their perceptions of a child's developmental skills and progress. These scales are helpful in clarifying ambiguous information provided during more formal observation and assessment. Ecological scales focus on the needs of the family and the quality of the learning and living environment for the child.

By staging an effective covergent assessment, a school psychologist can provide diagnostic information to determine a child's present level of developmental functioning in several different domains or skill areas in addition to a clear understanding of the child's strengths and limitations for determining goals and objectives to be included on the IFSP or IEP.

Testing without tests. LeVan (1990) proposes that standardized testing is an unnatural approach to the assessment of children with special needs. He suggests that observations of a child's natural skills, keeping a clear idea of typical and atypical developmental skills in mind, will provide the school psychologist and infant/early childhood educator with a rich source of diagnostic and prescriptive information. Using grocery shopping as an analogy, LeVan recommends that developmental evaluations can be completed using a shopping list of developmental expectations.

> In the market, goods are shelved in a somewhat orderly fashion based upon group or use. Although the precise arrangement may vary from market to market, there is a general pattern of organization that is recognized by most shoppers. To promote efficiency, the shopper prepares a list to guide the pursuit. Knowing the layout of the market may be helpful in preparation of the list and in procuring the goods. Of course, the list does not map out an exact route. You can start at any point, pick up items as you go, and come back to get what you missed. Bargains can be selected from special displays in any aisle and at any time. (p. 69)

Shopping for developmental skills can be accomplished in much the same way. Developmental skills may be considered in "orderly fashion" according to domain:

- Receptive language skills
- Expressive language skills
- Fine motor skills
- Gross motor skills
- Cognitive/play/early problem solving skills
- Social development
- Temperament

Understanding the "layout" or the patterns of typical development helps in preparing a list of developmental skills to be sampled, and the list ensures that assessment time is used efficiently to gain the necessary information. However, the "route" through the child's developmental skills is not dictated by an instrument or standardized set of procedures and "bargains" are frequent when a child exhibits behaviors spontaneously. Although a school psychologist or other evaluator can develop a list of domains and developmental skills, norm-referenced and curriculum-based measures can also provide samples of skills to be measured. Again, the emphasis in this approach is on the child's behavior and performance with a variety of tools and materials, not on a score on a test.

Neuromotor assessment. School psychology training programs generally do not include assessment of motor development. However, because rolling, sitting, crawling, and walking are major developmental milestones during the first 18 months of life, referral concerns for infant/toddler assessment and intervention often include motor delays. School psychologists can include neuromotor screening or assessment as a part of a comprehensive covergent assessment prior to making a referral to a physician or physical therapist. Several neuromotor screening or assessment tools are available to school psychologists including the Movement Assessment of Infants (Chandler, Andrews, & Swanson, 1980), the Chandler Movement Assessment of Infants-Screening Test (Chandler, in press), and the Milani-Comparetti Motor Development Screening Test (Milani-Comparetti & Gidoni, 1967). Although all require specialized training and extensive experience, neuromotor assessment falls well within the realm of a thorough developmental evaluation. A physical therapist can be helpful in assisting school psychologists with neuromotor screening.

Multiple sources. Information from parents, daycare providers, and medical charts or reports should be included as part of assessment/intervention. Multidisciplinary, transdisciplinary, and interdisciplinary assessment/intervention teams, mandated by IDEA, have become widely accepted methods of identifying the multifaceted needs of very young children. Information from assessment/intervention teams comprised of school psychologists, early intervention developmental specialists, speech pathologists, occupational therapists, physical therapists, and parents can provide a comprehensive view of a child's and family's strengths and needs. At times, two members may want to employ a "four-handed" approach to assessment (two professionals working with the child at the same time). One can keep the child engaged while the other observes, prepares materials, plans assessment strategies, interprets assessment procedures to parents, or elicits comments from the parent. Physical therapists and occupational therapists can be especially helpful to school psychologists working with children with physical disabilities by providing positioning and handling techniques to ensure optimal performance (Bagnato & Neisworth, 1991).

Arena evaluations. Transdisciplinary assessment programs may employ an "arena" approach to assessment/intervention (Woodruff & McGonigel, 1988). Although only one professional and the parent(s) interact with the child during an arena assessment, all members of a transdisciplinary team are present to observe and record information concerning the child's behavior and skills. While the child is expected to interact with only one unfamiliar adult, several or all team members have the opportunity to observe the entire evaluation and can offer a variety of behavioral and developmental perspectives to the assessment.

Multiple settings. The assessment environment can have a profound impact on a very young child's behavior. Infant/toddler assessment takes place in one or more of several locations including the child's home or day care setting, the public or private school building, and/or the clinic or hospital setting. Because young children usually perform better at home than in a school, clinic, or hospital setting, and because assessment of the home environment can be helpful in determining IFSP goals, the preferred assessment setting is in the more familiar environment. However, it can be helpful to observe the child's reaction to an unfamiliar setting during clinic/school/hospital evaluations.

Multiple occasions. Working with children over several sessions is essential with infants and young children. Accurate predictions and diagnostic information can be provided only in the context of progress with intervention over time. Patterns in skills can be observed only with multiple observations and assessment opportunities and will prevent inappropriate labeling and underestimating skill levels in children with developmental delays or disabilities (Bagnato & Neisworth, 1991). In addition, multiple assessment opportunities will allow the school psychologist to observe the dynamics of parent/infant interactions.

Not only are infants and young children sensitive to their environment, they are driven by their basic needs and states. Babies are often available for interaction for very short periods of time. They cannot perform for an evaluator if they are hungry, sleepy, or need a diaper change. Developmental evaluations can occur between diaper changing and bottles, but are seldom completed before an infant fusses for milk and a nap. Toddlers are often tired and fussy during the afternoons, especially if their regular routine includes an afternoon nap. Infant/toddler school psychologists must allow the child's state, needs, and regular routine to dictate the parameters of the assessment/observation session.

Interactive Strategies

Now for the "art" of working with young children: the quality of school psychologist/educator interactions with infants and toddlers during assessment can result in a range of possible outcomes from a clear image of a child's skills and needs on one end of the continuum to a frustrating and unproductive session on the other end. Fear of unfamiliar adults is developmentally appropriate for infants and toddlers. School psychologists can reduce this fear by interacting first with the parents. Children benefit when they have the opportunity to explore the environment or sit on the parent's lap for a few minutes before the evaluator attempts to begin the evaluation. For very slow-to-warm-up children seen in a clinic or school setting, the parents and the child may enter the examining room 5 to 10 minutes before the examiner to allow unrestricted exploration. Figure 5 provides additional interaction strategies to further reduce the effects of stranger anxiety.

> At 10 months of age (6 months adjusted age), J. K. was evaluated by the school psychologist. Although J. K.'s parents reported that he was able to reach out with both hands to grasp a rattle, the school psychologist found that J. K. kept his hands and arms back on the mat and did not reach out for the red ring when he was supine. The school psychologist attempted to encourage J. K. to reach for other, more attractive toys, but to no avail. J. K.'s mother offered her assistance by sitting on the floor and supporting J. K. in a sitting position between her legs. In this position, J. K. reached out actively for the rattle, the red ring, and his own stuffed dog, using smooth and symmetric movements.
>
> J. K. was again evaluated at 30 months of age. When the school psychologist rang the doorbell at J. K.'s home, J. K. ran to hide behind his mother's leg and refused to let go for the first 20 minutes of the visit. The school psychologist talked with J. K.'s mother, smiling occasionally at J. K. as J. K. reached around his mother's legs for a toy. The school psychologist moved to the floor and began exploring J. K.'s toys. When J. K. approached, to provide instructions about his favorite truck, the school psychologist listened attentively and introduced a toy from the bag of developmental assessment materials. J. K. cooperated with the school psychologist for approximately 40 minutes until he became hungry for lunch. Another appointment was scheduled within the week to complete the evaluation.

Report Preparation

Psychological reports are often organized according to tests administered to identify cognitive abilities, academic achievement, processing deficits, and/or emotional disabilities. This traditional format is not appropriate for infant/toddler reports because it fails to communicate information that would be applicable for early intervention programming. Developmentally based reports (Bagnato & Neisworth, 1991) work better because they are organized with headings identifying developmental domains, medical information and recommendations, behavioral obser-

FIGURE 5. Working with very young children.

- Incorporate the child's toys into the developmental evaluation.
- Encourage parents and siblings to assist in eliciting developmental skill. Provide explicit instructions about the developmental skill and possible ways to detect that skill.
- Begin with a brief warm-up period. This period should be long enough to allow the child to engage with the examiner but not so long that the attention span of the child is overtaxed (Paget, 1983).
- INfants and children with significant physical needs perform to the best of their ability when they are placed in comfortable positions in which their attention and physical movements are not restricted. Infants should be placed in the most mature position possible; children with significant physical needs should be positioned with the assistance of parents or physical therapists.
- Infants and very young children provide a small window of opportunity for assessment. Close attention to timing of item presentation is essential to maintain the child's attention and willingness to work. Developmental tasks should be introduced quickly enough to retain the child's attention but not so quickly that the child is overstimulated. Although the examienr should be ready with the next task, the child should not be rushed to move on before completing work with the previous task.
- When working with very young infants or those with significant developmental delays, it is often helpful to dim the lights and reduce extraneous noise or other stimuli. Gentle handling can increase the observation opportunities by reducing the amount of time the examienr or parent must spend comforting a crying or upset baby.
- Some toddlers, especially those who are noncompliant to instructions, will perform when given a choice of activities. In a clinic or school setting, developmental activities can be distributed throughout a large room. The school psychologist can gain a great deal of useful information by observing how children make choices among the activities, how they move from one activity to another, and how long they are able to maintain attention to a single task before moving onto the next activity.

---

vations, and curricular/family goals. Under each heading, information from difference sources can be integrated to provide a clear description of a child's strengths, limitations, and programming needs.

Professional reports seldom communicate in "parent friendly" terms (Bagnato & Neisworth, 1991). Clinical jargon and the use of technical language must be avoided in reports. Even commonly used terms such as "expressive and receptive language," "muscle tone," or "etiology" can be intimidating for parents (Parker & Zuckerman, 1990).

SUMMARY

School psychologists are a valuable resource in the evaluation process with infants and toddlers. Adequate preparation is critical, because evaluating infants and toddlers requires different skills and expectations than those taught in traditional training programs. With appropriate training and experience, school psychologists can be fully prepared for the responsibilities involved in infant/toddler assessment and can function as valuable members of the assessment team.

Because of dramatic developmental changes and behavioral fluctuations of infants and toddlers, psychologists are asked to rely more on professional judgment and the knowledge of parents and other team members in understanding a child's developmental needs. The limited utility of traditional assessment instruments at this level requires the use of multiple measures, sources, settings, and occasions to address the assessment goals. Families must have the opportunity to be full participants in all phases of the evaluation/intervention process. The emphasis is on family-centered decision making and assessment as an initial step in the intervention process. Providing an additional challenge, infant/toddler school psychologists must be comfortable with medical issues that confront young children with disabilities. Participating in the team assessment/intervention process of infants and toddlers is an exciting and important new role for school psychologists.

ANNOTATED BIBLIOGRAPHY

Bagnato, S. J., & Neisworth, J. T. (1991). *Assessment for early intervention: Best practices for professionals.* New York: Guilford Press.
The role of the family in assessment and intervention of infants and toddlers is emphasized in IDEA. This book, which has been described as "essential reading" for school psychologists and early intervention specialists, provides a clear understanding of how parents and professionals can work together to assess a child's needs and design an appropriate educational program. The focus of the book is assessment for early intervention; the scope of the book moves beyond test administration and interpretation to describe family-focused assessment in which the child's developmental skills and needs are the emphasis. Covergent assessment is discussed in detail as well as testing without tests, curriculum-based developmental assessment, and professional/family collaboration.

Blackman, J. A. (1990). *Medical aspects of developmental disabilities in children birth to three (2nd ed.).* Rockville, MD: Aspen.
School psychologists involved in infant/toddler assessment/intervention will meet a new challenge in dealing with the significant medical needs of these children. This book provides a summarized compilation of medical information related to children with special needs. In clear, easily understood chapters, Blackman provides descriptions, causes, incidence, methods of detection, and implications for education of nearly 40 medical conditions that occur in infants and toddlers with developmental delays or disabilities. Included in the chapter are prevalent conditions with which school psychologists often have knowledge and experiences including Down syndrome, myelomeningocele, anemia, and sensory impairments in addition to some conditions which may be new to psychologists just becoming involved in early intervention including congenital infections, bronchopulmonary dysplasia, environmental teratogens, and perinatal injury.

Cohen, M. A., & Gross, P. J. (1979). *The developmental resource: Behavioral sequences for assessment and program planning (Vol. 1).* New York: Grune & Stratton.
Cohen and Gross translate the literature on a variety of developmental skills into sequences of developmental tasks from birth to 6 years of age across multiple domains, including sensorimotor/early cognitive, gross and fine motor, language, social, and self-help/adaptive living skills. This book provides a base of typical infant/child development from which to build a "shopping list" of skills to observe during developmental evaluation.

Flehmig, I. (1992). *Normal infant development and borderline deviations: Early diagnosis and therapy.* New York: Thieme.
School psychologists must be familiar with normal and deviant patterns of development when evaluating infants and toddlers. This book details normal motor development from birth to 18 months, neuromotor assessment strategies, and clear descriptions of deviating motor development in infancy. Photographs of infants provide clear understanding of primitive reflexes and normal and aberrant motor development. A chapter on handling includes tips for appropriate and inappropriate handling of infants, especially those with neuromotor problems. This is an excellent guide for school psychologists who will be involved with infant assessment.

Gibbs, E. D., & Teti, D. M. (1990). *Interdisciplinary assessment of infants: A guide for early intervention professionals.* Baltimore: Paul H. Brookes.
Assessment/intervention with infants involves understanding a variety of skills and behaviors. Information concerning infant neuromotor assessment, cognitive/language/developmental assessment, social assessment, and the assessment process is comprehensively compiled in this book, providing a valuable resource for educators and school psychologists.

Harrison, H. (1983). *The premature baby book: A parents' guide to coping and caring in the first years.* New York: St. Martin's Press.
Premature babies comprise a large subsection of the infants and toddlers considered "at-risk" under IDEA. Although many premature babies develop normally, developmental and neuromotor monitoring is important during the first years of a premature baby's life. This book is designed for parents of premature babies but can be useful to school psychologists or other team members who are involved with assessment and intervention of infants and children. Chapters include information about how parents cope with the birth of a premature baby, medical problems that arise with premature deliveries, and developmental delays associated with prematurity.

Best Practices in the Academic Assessment of Secondary Students

Kathryn Clark Gerken
The University of Iowa

OVERVIEW

"Ten years after *A Nation at Risk*, we still lack the will and commitment to reduce the risks that imperil our children" (Crosby, 1993, p. 598). Crosby also states that it is as if society is allowing a school bus full of screaming children to slide out of control down an icy hill. I believe that school bus contains children of all ages, but the adolescents in that bus may be at an even greater risk than the other children. Adolescence is typically associated with great risks in the area of health and education. Takanishi (1993b) reports that adolescents today face greater risks to their current and future health than ever before. For example, mental disorders are the major cause of disabilities among adolescents ages 10 to 18 (National Center for Education in Maternal and Child Health, 1990); more adolescents, especially before age 15, are experimenting with drugs (Gans & Blyth, 1990); U.S. adolescents are unique among adolescents in developed nations in their exposure to violence, especially homicide (Hammond & Yung, 1993) and in their rates of pregnancy (Moore, 1992). Poverty, homelessness, and disintegration of families have all increased. A current review of research on adolescent development suggests that the early adolescent years mark the beginning of a downward spiral for some individuals, a spiral leading to academic failure and school dropout (Eccles et al., 1993). Hahn (1987) reports that overall dropout rates for adolescents may not have increased, but the dropout rates in large cities range from 40 to 60% of the population. Dropout rates are much higher for adolescents who (a) come from low-income and single-parent households; (b) are behind in grade level and older than classmates; (c) have poor academic performance; (d) have frequent detentions and suspensions; (e) are pregnant; (f) believe that work or military service is their only alternative to failure in school; or (b) have learning disabilities, emotional problems, and language difficulties.

Whether the situations confronting today's children are called "childhood genocide" (Reynolds, 1992) or a waste of lives (Hahn, 1987; Takanishi, 1993a), it is clear that changes are needed. Multiple layers of structural change are needed. Only by working together across the boundaries created by society (school vs. community vs. family, etc.) can today's educators hope to effect positive changes in the lives of a large number of adolescents. It is imperative that all education professionals make a commitment to support the full development of all adolescents into productive adults. Crosby (1993) states that in the land of the free, many of our children are not free:

> Some are not free to receive equal opportunities. Some are not free because they are minorities. Some are not free because of poverty. Some are not free because they are teenage mothers. Some are not free because their families have disintegrated. Some are not free because of violence, drugs, and guns in their environment. All of them are not free because we are not willing to free them. (p. 604)

The seriousness of the problems encountered during adolescence is magnified for those adolescents already at risk. The results of the 1992 National Assessment of Educational Progress (NAEP; Elliott, 1993) shows that, for students in the eighth grade, there were significant decreases in mathematics performance for "disadvantaged urban" students' average proficiency as well as for the proportion of these students at or above the basic level. Foertsch's (1992) report on the 1990 NAEP reading assessment focused on the factors influencing literacy achievement. She found that the amount of reading students did in school and the amount of reading that students did out of school were positively related to their reading achievement. Yet, students reported doing relatively little reading in school or out of school. It was also found that students who reported more home support for literacy had higher average achievement. Students reported somewhat less access to reading materials in the home in 1990 than in 1988. Foertsch (1992) also reported that in spite of extensive research suggesting that effective reading instruction includes moving toward more opportunities for combining reading and writing activities, workbooks remain a prevalent approach to instruction in reading. Students in fourth, eighth, and twelfth grades all had difficulty in constructing thoughtful responses to questions asking them to elaborate or defend their interpretations. Also, as the grade level increased, the frequency of the use of the library decreased. The majority of the eighth graders said they went to the library on a monthly basis and most twelfth graders reported only yearly use of the library.

School psychologists who work with adolescents can begin to "free" some of the at-risk adolescents by utilizing a problem-solving approach in which interventions are student specific and outcome focused. There are a variety of problem-solving models in existence. However, the steps in the IDEAL (Bransford & Stein, 1984) model are the basic steps in every model: **I**dentify the behavior; **D**efine the Problem; **E**xplore intervention options; **A**ct on the plan; and **L**ook at results. The Department of Education, State of Iowa (1993) believes that the critical components of the problem-solving process are parent involvement, problem statement, systematic data collection, problem analysis, goal, intervention plan development, intervention plan implementation, progress monitoring, and decision making. Problem-solving practices can be used to identify problems and intervene with large numbers of students or with individual students, but they must be adapted to fit the nature of the problem. Solving one problem at a time in cooperation with the adolescent, his or her family, and the community should lead over time to the desired structural changes in America's schools, families, and communities.

The purpose of this chapter is to provide guidelines for assessing the academic skills of adolescents. It is apparent that academic assessment should not be done in isolation. Therefore, a comprehensive assessment process that leads to effective intervention is presented.

BASIC CONSIDERATIONS

Huebner (1993) reporting on the results of a national survey of school psychologists serving secondary schools, noted that approximately three-quarters of them were satisfied with their functioning in the secondary schools. The data suggested that job satisfaction increased as time spent conducting individual and family counseling increased and time spent in assessment decreased. Thus these results appear similar to those in the 1970s that said psychologists were dissatisfied with spending much of their time conducting assessment. An unknown regarding this survey is how assessment was defined. It is also interesting to note which special skills or knowledge the school psychologists thought should be in a training program and what the psychologists perceived as their three greatest needs in terms of professional development. Counseling was the most frequently listed component for a training program (73 persons), then crisis intervention (36) and consultation (29). (In fifth place was adolescent psychology [19]. Despite the fact that professionals increasingly recognize how little is known about adolescent development, these respondents were more interested in specific learning techniques than the foundation upon which these techniques should be based.) The greatest needs the psychologists reported were, in order, general counseling skills (46), crisis intervention (26), and consultation (23). Huebner (1993) concluded that school psychologists need to be prepared to offer a diversified array of professional services.

The best way to be prepared to offer a diversified and appropriate array of services is to

- Have an understanding of the school environment and the social environments in which adolescents live.
- Have knowledge of current research in adolescent development, theories of learning, basic measurement theory, and the theories underlying skill development in reading, writing, and arithmetic.
- Have supervised experience in applying this knowledge during coursework and field experiences.

A psychologist working with adolescents needs to be interested in adolescents and knowledgeable about their interests and needs if he or she hopes to prevent the steep decline in academic and social behavior observed in many adolescents (those already receiving special services; those not identified earlier; those already lost to dismal, intractable academic failure; and those who have serious social/emotional problems). Eccles et al. (1993) argue that optimal development takes place when there is a good stage-environment fit between the needs of developing individuals and the opportunities afforded them by their social environments. It is the responsibility of school psychologists and other professionals who work with adolescents to try to help teachers and parents provide an environment that changes in the right way and at the right place. This is a difficult task, but one school psychologists should be academically and experientially prepared to handle. A needs assessment within the school, classroom, and home should be conducted to determine the interest and support of administrators, support personnel, classroom teachers, and parents for improving academic assessment and intervention for adolescents. Junior and senior high school teachers often feel overworked and harried and unable to give individual attention to students (feelings often shared by parents of adolescents). To be effective in meeting the needs of adolescents with academic problems, the school psychologist must first be effective in determining ways to "fit" improved assessment and intervention into the already existing culture of the school and home rather than assuming the culture can be changed.

School psychologists need to continuously update themselves relative to research on adolescent development; academic and social curricula for adolescents; and technology used to set up screening, assessment, and intervention programs.

BEST PRACTICES

Screening and diagnosis of academic problems must be improved because too many adolescents have academic skills far below their age-mates before intervention is attempted. There is no reasonable justification for this because empirical support exists for providing early intervention to prevent or at least reduce some of the negative effects of academic difficulties.

Definitions

There are numerous terms for referring to the collection of data used to describe an individual's or group's level of knowledge, performance, or achievement. *Assessment, evaluation, measurement,* and *test* are the terms most frequently used. Sometimes they are used interchangeably when they should not be. Wood (1987) states that "assessment is regarded as providing a comprehensive account of an individual's functioning in the widest sense — drawing on a variety of evidence, qualitative as well as quantitative, and therefore going beyond the testing of cognitive skills by pencil-and-paper techniques, which for many people is measurement" (p. 2). Webb (1992) states that in education the term measurement is restricted to a quantitative description of student behavior. He believes evaluation is the systematic collection of evidence to help make decisions regarding students' learning, material development, and program. For the purpose of this chapter, problem-solving assessment refers to the comprehensive accounting of an individual's functioning within the academic areas or in the application of academic skills. Problem-solving assessment is an approach used to collect the data needed to solve problems for individuals or groups. Testing, measurement, and evaluation are important aspects of that approach.

Disability versus Deficiency

Many adolescents exhibit significant difficulties in academic work. It is extremely important to pinpoint the sources of these difficulties and identify and define the specific problem. Appropriate intervention may be dependent on whether the student is having difficulties due to

- Environmental factors such as limited exposure to the material, cultural expectations based on student characteristics, and inadequate instruction.
- Individual characteristics such as limited ability to think abstractly, anxiety and other affective concerns, inefficient learning strategies, inability to retrieve information, poor attention span, low motivation, impaired communication, and the like.
- The interaction of environmental and individual variables.

The intervention plan for a student with a deficiency in math due to not ever having spent the time necessary to master the basic multiplication facts will differ from the plan for the student who has spent considerable time attempting to master the multiplication facts but has a specific disability in retrieving nonmeaningful material. A specific disability would require that in addition to a positive and effective instructional environment, compensatory skills be developed. Whereas, a student who has an academic deficiency but not a specific disability may simply need to receive effective instruction for the existing gaps in academic skills and/or be taught appropriate study skills. Assessment and intervention in the 1990s still need to be individualized.

Screening

Reynolds (1992) believes that literacy, social and civic behavior, and self-dependence are the cultural imperatives in modern America. Schools are being challenged to teach all students in the domains of these cultural imperatives; yet many times the students' difficulties in these areas are not identified at the incipient stage and become "serious" or "severe" before intervention begins. The information needed to screen for problems in these areas is usually already available as is the technology to make such information accessible. Four curriculum areas appear to accommodate the needs of all secondary age students: (a) academic knowledge and skills; (b) vocational knowledge and skills; (c) independent living knowledge and skills; and (d) social knowledge and skills. A thorough assessment and intervention plan for an adolescent must begin with screening for problems in each of these areas and then focus on the area of greatest need. (Assessments of adaptive behavior, social/emotional status and vocational skills are covered in other chapters in this book.) A screening system should be in place at every school level, but it is imperative for adolescents. Educational professionals cannot wait for adolescents to be referred or be placed in more restrictive environments before attempting to pinpoint their academic problems and effecting positive changes for them.

Gerken and Winslow-Garvin (1993) created an "early warning system" to identify at-risk students:

- Classroom teachers completed a School Behavior Rating Scale for every student.
- Support teaching staff (art, media, music, and physical education) selected students the staff believed to be "at risk."

- Parents were asked to complete a Home Behavior Rating Scale.
- The students in Grades 2 to 6 completed the Piers-Harris Children's Self-Concept Scale.
- File reviews were conducted to record absences, number of school changes, health problems, frequent trips to the office because of health complaints, information on whether the students were on medication, reports of academic difficulties, test scores, reported social/emotional difficulties, removal from classroom, parent and teacher comments regarding academic and/or social difficulties, classroom management plans, intervention within the classroom, intervention outside of the school, letters to and from parents regarding academic and/or behavioral concerns, removal from the classroom and/or school, referrals for special services within or outside the school (child study team, speech, Chapter 1, ESL, school psychologist, guidance counselor, social worker, etc.).

The four major sources of information about the students were teachers, parents, self, and cumulative folders. Students were identified as "in need of intervention" if their names appeared on the at-risk list from at least two of the four sources. Verification of need for intervention was done by communicating with all concerned persons. Reynolds, Zetlin, and Wang (1993) created a "20/20 Analysis" to identify students showing the least (below 20th percentile) and most (above 20th percentile) progress toward important objectives of education in a school. The steps for performing 20/20 analysis were

1. Select a dimension of learning to be used.

2. Identify the grade and school-wide percentile distribution compared to national norms.

3. Identify the percentile cutoffs of the high 20% and the low 20% for each grade level.

They chose reading as the dimension of school learning for analysis because it was a major concern of the school staff with whom they were working. Although some students receiving special education services were not identified via this method, it did uncover others not receiving services who would benefit from intensive help in basic subjects. Of the students scoring below the 6th percentile (national) in reading, 68% ($n = 89$) were not receiving any intensive forms of instruction. A secondary school could build other steps into this approach which would verify the need for intervention. This chapter's Appendix A presents a model for assessing the academic skills of secondary students that is based on the research presented here and on the author's experiences working with students and schools.

It is necessary to check health, vision, and hearing before initiating other assessment. Task-related skills, vocational goals and skills, and social skills of secondary students are all part of the academic assessment process.

Diagnosis

If the secondary school has a screening process in place, the general problem area will be identified. However, with or without the screening process, it will be necessary to pinpoint the problem area, conduct appropriate assessment, determine priorities and resources for intervention, initiate changes needed, monitor progress, and initiate additional changes if needed. The purpose of assessment at any level is to effect positive changes for the person with the presenting problem. The assessment "tool box" of school psychologists should contain many different tools, as the actual assessment conducted should be dependent on the specific problem that needs to be solved. Far too often information is collected that education staff already possess, do not need, or will not use. Many times assessment may never need to go beyond direct observation and record review.

Numerous individual and group achievement tests were developed or revised in the 1980s in an attempt to improve their standardization procedures, make the format and content more relevant to what is being taught in the schools, and use alternative techniques to pinpoint areas of concern. Many students' academic needs are being ignored because there is insufficient direct observation, review of work samples and past records, use of interviews, error pattern analysis, task analysis, checklists, self-report inventories, and curriculum-based assessment. Valencia, McGinley, and Pearson's 1990 chapter on literacy assessment provides basic guidelines for good assessment across all basic skill areas. They state that assessment needs to be put back in the hands of those most affected by it — students and teachers — and that assessment should be a natural part of the teaching/learning process, not something added on or imposed as an afterthought. The emphasis in the 1990s is on contextualized assessment (Ruddell, 1993; Valencia et al., 1990) that has the following attributes:

1. Focuses on learning.

2. Is equitable.

3. Is consistent with the aims of the system, the school, and the curriculum.

4. Recognizes the limitations of assessment methods.

5. Reduces competition and increases cooperation in the classroom.

6. Includes participation by students.

7. Includes consistent and meaningful reporting.

8. Is continuous.
9. Is multidimensional.
10. Is collaborative.
11. Must be grounded in knowledge.
12. Must be anchored in genuine tasks and purposes (authentic).

Appropriate assessment should result in

1. Insight into the substance and extent of students' content knowledge.
2. Understanding of which literacy skills students need to learn in order to function effectively in various subject areas.
3. An indication of what the teacher needs to do to assist or guide students in the classroom.
4. Identification of students who may need additional evaluation or assistance outside the classroom.

If the screening process has indicated a student has an academic problem, the diagnostic process in Appendix A needs to be implemented. Parents/guardians should be involved in the screening process and in every step of the diagnostic process. A decision must be made as to which additional techniques will be used to collect data and who will collect the data. School psychologists, parents, other support personnel, and classroom teachers need to work together to determine what information each will gather. The classroom teacher will usually be better prepared to do curriculum-based assessment in a content area than the school psychologist. But the school psychologist may have a better understanding of the psychology of learning and can serve as a consultant in both the assessment and intervention phases.

Reading

The most essential basic skill needed in any school curriculum is reading; yet content area teachers often find themselves confronted by students who vary considerably in their development of and ability to apply the skills necessary to read and understand content area materials. Thus, it becomes imperative that content area teachers learn to recognize the extent to which students can apply reading skills to the printed materials they encounter. Farr, Tully, and Pritchard (1989) state that there are six categories of information content area teachers need to know about their students in order to plan for instruction:

- Students' instructional reading levels.
- Strategies that students use when they encounter specialized or technical vocabulary.
- Students' competence with literal, inferential, and critical levels of comprehension.
- Students' background knowledge of the subject area.
- Students' skills with study techniques.
- Students' interests and attitudes.

Often, content area teachers have not had coursework on the reading process or on the assessment of reading skills. Thus, school psychologists need to assist the teachers in determining if students have the skills necessary to succeed in a particular content area. How can such determinations be made? Henk (1993) believes that the contemporary view of reading has forced education professionals to look beyond diverse aspects of the reader to other critical reader variables such as prior knowledge of the topic; attitude towards reading; school and home-based reading habits; topical interests; and the use of before-, during-, and after-reading strategies. He also makes it clear that the analysis does not stop with the reader. Text variables such as conceptual difficulty, genre, organization of the text, its physical features, author's style and intent, and the appeal of the text must be examined along with contextual variables such as where and when reading takes place, the purpose of the reader, the nature of the task, and the reader's previous or current instruction.

The contemporary view of reading is that it is a dynamic interaction among the characteristics of the particular reader, the attributes of a specific text, and the context in which the reading occurs (Henk, 1993). The assessment of reading must go beyond the administration of any one assessment tool. It has been generally accepted that assessment of prior knowledge will contribute to a reading diagnosis, but no one method of assessment has been agreed on. Reading strategies are also viewed as important components of the reading process, but there has been little done on assessing reading strategies.

Three assessment tools that aspire to assess reading processes versus products are miscue analysis, a system for evaluating oral reading errors; think alouds, a form of verbal self-report; and inserted questions, questions embedded within a passage to assess hypothesis testing and prediction abilities. Miscue analysis and think alouds have been used in reading assessment, whereas inserted questions have been used more for instruction than assessment. Additional assessment tools that have recently emerged are the use of authentic texts; assessment of reading habits and attitudes; and informal, dynamic, and portfolio assessments.

Informal Reading Inventories (IRIs). The assessment of the reading skills of secondary students can be done thoroughly only if the informal reading inventory used is based on the student's content area skills. A format developed by Readence, Bean, and Baldwin (1983) contains the sections of a typical Content Area Reading Inventory (CARI):

I. Textual Reading/Study Aids
  A. Internal aids
    1. Table of contents
    2. Index
    3. Glossary
    4. Chapter introduction/summaries
    5. Pictorial information
    6. Other pertinent aids
  B. External aids
    1. Card catalog
    2. Reader's guide
    3. Encyclopedias
    4. Other pertinent aids
II. Vocabulary Knowledge
  A. Recall
  B. Contextual meanings
III. Comprehension
  A. Text-explicit information
  B. Text-implicit information
  C. Author organization

Farr, Tully, and Pritchard (1989) report that each main section of a CARI contains 20 to 25 questions. Each section uses the student's textbooks. The comprehension section is a passage about 3 or 4 pages in length taken from the textbook. Both literal and inferential questions are to be asked. The CARI is used to examine performance in responding to the different kinds of tasks. The teacher sets the criteria for determining whether the students can successfully complete the reading and study tasks required in a course or unit of instruction.

Other Informal Reading Inventories (IRIs) are developed from students, textbooks, or any other reading materials. The IRIs are used to determine independent, instructional, and frustrational levels of reading. General guidelines for developing more traditional IRIs are available in Hammill and Bartel (1990). Critical reviews of the use of IRIs suggest that several problems limit their use:

- The criteria for evaluating IRI performance are subjective and arbitrary.
- Selecting passages from a graded reading will not accurately guarantee a progressing range of reading difficulty.
- The examiner needs to have considerable knowledge about reading in order to record errors and make judgments about a student's performance.
- IRIs are not as useful at the upper grade levels as they are at the lower grade levels because of differences in reading material.
- Background information takes on greater importance.
- Oral and silent reading appear to be less similar at the upper grade levels (Farr & Carey, 1986).

Decoding. The relationship between decoding and comprehension is not a simple one, as each enables the other and neither should be ignored. The four subskill areas that need to be examined in word recognition skills are basic sight vocabulary, phonics, structural analysis, and word meaning. When measured, word recognition should be assessed in a way that enhances instruction. A majority of reading tests contain word recognition subtests, but just as there are numerous theories and methods of teaching word recognition, there are numerous testing methods also. Knowledge of the meaning of words is considered by many to be the most important of the word recognition skills. Word recognition skills should be assessed on context as much as possible. Therefore, do not use nonsense words to determine the word recognition skills of adolescents. Any word recognition test should be considered just a sample of the many word recognition behaviors that could be tested. The test should be of adequate length to ensure stable results.

Howell and Morehead (1987) provide a format for evaluating decoding that was adapted here for assessing the secondary-age student (see Appendix B).

Comprehension. There are six common approaches to measuring comprehension: (a) asking questions requiring either recall or recognition answers; (b) having students paraphrase; (c) having students retell a story exactly as heard; (d) having students fill in missing words (cloze technique); (e) having students select the correct word to complete a sentence (mazes); and (f) asking students to read for one minute each of three different 250-word passages that have been selected from their own curriculum (oral reading rate).

Howell, Fox, and Morehead (1993) indicate that there is no simple best procedure for assessing comprehension and that one needs to use more than one method across texts of various styles. They have developed a "Comprehension Status Sheet" which helps identify the comprehension strategies and enabling skills a student has. If the results of survey tests indicate that comprehension is a problem, comprehension within the student's own materials should be assessed. Is the student having comprehension problems because of a deficit in background knowledge, decoding skills, vocabulary, language syntax, or comprehension strategies? General and specific guidelines for determining the cause of the problem (Choate et al., 1992; Howell et al., 1993) and for planning interventions (Choate et al., 1992; Howell et al., 1993; Masters, Mori, & Mori, 1993) are available.

Written Expression

Poteet (1980) defines written expression as "a visual representation of thoughts, feelings, and ideas using symbols of the writer's language system for the purpose of communication or recording" (p. 88). The components of written expression are usually thought of as handwriting, spelling, mechanics, usage, and ideation. It has been generally accepted that there is a hierarchy of written expression and that the expression of ideas through writing is the last of the skill areas acquired by students. However, a view of writing as an interrelated set of motoric, cognitive, and social responses has emerged during the 1980s and 1990s. This view has had an impact on the way writing is taught (Morocco, Dalton, & Tivnan, 1992) and should have an impact on the way it is assessed.

The minimum desired competencies in written expression are that students write legibly and express their thoughts in writing well enough for others to understand them. If concern about any aspect of written expression is noted during the screening process, the steps outlined in Appendix A need to be carried out.

It is necessary for the psychologist to know (a) which writing skills have already been introduced to the student, (b) which skills are appropriate for the student's grade placement, (c) the requirements of the writing tasks the student has failed, (d) the intervention programs and techniques available to the student, and (e) the student's desire to perform writing tasks.

It is possible to use the student's role in communication as an instructional and assessment tool. Students need to make the purpose of their writing clear; participate in the processes of planning, reviewing, revising, and transcribing; and produce a product that is accurate and easily understood. Fluency, syntactic maturity, vocabulary, content, and writing conventions can each be observed and measured. Formal and informal assessment techniques have been used to assess these products. If writing is viewed as an integrated process, then the assessment of it should occur when students are completing a variety of writing tasks.

Morocco, Dalton, and Tivnan (1992) report that good writing instruction includes (a) engaging students in the full composing process; (b) engaging them in a real intent to communicate; (c) helping students become fluent in expressing their ideas; and (d) fostering listening and peer response skills. These principles can be met only if there is balanced instruction which includes explicit instruction in the writing process and explicit instruction in the mechanics of writing. Fluency, sentence combining, and accuracy are also aspects of writing that must be taught. Choate et al. (1992), Howell et al. (1993), Ruddell (1993), and Valencia et al. (1993) contain excellent inventories, surveys, scales, checklists, charts, and sample items that can be used in writing instruction and assessment. "Assessment, Consultation and Intervention for Writing Problems" is a useful annotated bibliography (Berninger & Hooper, 1993).

Mathematics

Despite the general improvement in students' mathematics performance on the National Assessment of Educational Progress (NAEP) between 1990 and 1992 (Mullis, Dossey, Owen, & Phillips, 1993), large disparities exist across demographic groups. More than one-third of the students at Grades 4, 8, and 12 did not reach the lowest level of performance and no statistically significant increases were found at the Advanced Level. Seniors from the bottom-performing one-third of the schools appeared to be less mathematically proficient than the eighth graders in the top one-third performing schools.

Bottge and Hasselbring (1993) report that adolescents with a history of difficulties in mathematics have a greater risk of finishing school without the necessary skills to function in everyday life. Therefore, it is imperative that appropriate mathematics assessment take place. Webb and Briars (1990) state that assessment should occur in a variety of situations, include a variety of mathematical representations, and involve the use of calculators and computers. The assessment information should be used to determine students' perceptions of mathematical ideas and processes, determine their ability to function in a mathematical context, and guide instruction.

Changes in mathematics assessment procedures have been influenced by the overall movement in the assessment arena to make assessment more "authentic." However, the Curriculum and Evaluation Standards (National Council of Teachers of Mathematics [NCTM], 1989) and the Professional Standards for Teaching Mathematics (NCTM, 1992) have had a more powerful influence on the persons who should know most about mathematics teaching and assessment, the classroom teachers. Thus, the assessment likely to be most effective is an interaction between teacher and student, with the teacher continually seeking to understand what a student can do and how the student is able to do it, and then using that information to guide instruction.

If the screening process had indicated that a student has a problem in mathematics, the steps outlined in Appendix A under the diagnostic process need to be carried out: determination of academic expectations in mathematics, observations, interviews, curriculum-based assessment, and informal analysis of responses. The results of the most recent group achievement test would give a general idea of a student's functional level in mathematics. An individually administered standardized mathematics test should be given only if there is a technically adequate one available that assesses the important components of mathematics that this student is expected to master. Numerous tests have been developed as diagnostic math tests, but few provide enough information regarding strengths and weaknesses to plan intervention.

The guidelines for teachers' assessing students' understanding of mathematics (NCTM, 1991) should be followed by anyone conducting mathematics assessment: (a) use a variety of assessment methods; (b) match assessment with the developmental level, mathematical maturity, and cultural background of the student; (c) analyze the student's understanding of and disposition to do mathematics and provide this information to students, parents, and pertinent school personnel; and (e) base instruction on assessment.

These guidelines can best be followed by assessing the student in his or her own curriculum. Various alternatives to standardized formal mathematics assessment are available and should be used if they provide a much better assessment/instruction match.

Just as a new assessment vocabulary developed in the 1980s, constructivism became a widely accepted theoretical position in mathematics education. What that means from a practical instructional view is that teaching skills from explaining or telling to facilitating the development of students' knowledge structure or co-constructing knowledge with the student. Although this approach is not new to everyone, it does require a significant shift in the teacher's responsibilities to the student and an increase in the complexity of decision making in teaching. When does one "tell" versus "co-construct?" How does one decide what a student does or does not understand? It is a lot easier to teach and assess via a strict behaviorist approach in which the product or response is what is important, not the process or understanding of the response. However, such teaching and assessment is not considering the students' prior knowledge and the processes that may already be in place. Arcavi and Schoenfield (1992) state that, above all, the constructivist approach demands that educators listen very carefully to what students have to say. This is also true in the assessment arena.

Lesh, Lamon, Behr, and Lester (1992) discuss future directions in mathematics assessment and provide a very detailed table that summarizes some of the important differences between traditional standardized testing and performance assessment activities. They point out that, in general, traditional types of standardized tests have only dealt with a narrow range of decision-making issues and have been based on outdated conceptions of mathematics. Yet, the alternative assessment movement has focused on using the measures as a leverage point for curriculum reform and given little attention to issues such as fairness and reliability in scoring, the usefulness and credibility of results for some decisions and the scope and representativeness of the constructs that are measured when looking at the quality of a collection of tasks. Lesh and Lamon (1992) believe that curriculum reform efforts (and in turn assessment efforts) need to

- Go beyond testing (for screening) to assessment (for informal decision making).
- Go beyond a few discrete assessment events to the seamless integration of instruction and assessment.
- Go beyond behavioral objectives to cognitive objectives.
- Go beyond multiple-choice tasks to realistic tasks.
- Go beyond right answers to reasoned answers.
- Go beyond one-number scores to multi-dimensional profiles.
- Go beyond report cards to learning progress maps. (Lesh & Lamon, 1992, p. 15)

Relative to assessment and instruction/remediation in mathematics, technological aids (calculators, computers, interactive videos) have proven to be useful (Bottge & Hasselbring, 1993; Fey & Hirsch, 1992; Hopkins, 1992; Thomas, 1992). Numerous resources for mathematics projects and activities can be used as assessment and intervention techniques (Choate et al., 1992; Cooney, 1990; Fey & Hirsch, 1992; Hammill & Bartel, 1990; Howell et al., 1993; Mathematical Sciences, 1993; Thomas, 1992).

Science, Social Studies, and Other Academic Courses

If there is concern about any other academic area, the steps outlined in Appendix A should be carried out with the specific or personalized assessment focusing on the content of these courses and on determining skills in reading, vocabulary, problem solving, use of graphic aids, study strategies, and social skills.

Task-Related Skills/Strategies

Terms such as study skills, habits, tactics, and strategies have been used to describe techniques and strategies that assist a student in adequately and efficiently completing the educational tasks associated with the learning components. Hoover (1988) identifies several learning components affected by the use of study skills: (a) acquisition, (b) recording, (c) location, (d) organization, (e) synthesis, (f) memorization, and (g) integration of these components. The assessment of task-related skills and strategies can be done via norm-referenced and/or informal assessment techniques. Most of the multiskill group achievement tests have a study skill component. However, just as in every other area discussed in this chapter, the most effective assessment tool is one that is personalized and specific to the needs of the student or class involved. The steps outlined in Appendix A should be followed. Rakes (1992), Hammill and Bartel (1990) and Howell et al. (1993) contain excellent guidelines for assessing task-related skills/strategies. For example, Hammill and Bartel (1990) have created a Study Skills Inventory; Choate et al. (1990) a Teacher Survey and an appendix with study strategy objectives and sample test items; and Howell et al. (1993) a Status Sheet for Task Related Knowledge. (Also, the chapter in this book by Harvey contains guidelines for teaching study skills.)

Vocational Goals and Skills

A significant number of adolescents leave school without having mastered the skills needed to successfully obtain and maintain employment. Vocational goals and skills should be assessed long before a student is ready to enter the world of work. Information about vocations and integration of interests, aptitudes, and goals should be introduced no later than middle school. Levinson's chapter in this book deals specifically with vocational assessment, but the steps in Appendix A should be carried out with any secondary student with academic concerns. Such assessment can be done via formal and informal assessment techniques, but if done in the context of students' regular coursework, then informal techniques would be most appropriate.

Social Skills

Gresham covers the area of social skills training and assessment of social/emotional functioning in this text. I have introduced the topic in this chapter because direct observation in classrooms with adolescents has made it clear that academic achievement problems and social/emotional difficulties are not easy to separate. They may be acting directly or indirectly on each other, have no relationship whatsoever, or be so intertwined that it is not possible to determine which came first. Long-term problems without intervention in either area are likely to affect the other. There are far too many students with a history of academic difficulties being identified as students with behavior difficulties when they reach adolescence. Assessment and intervention in this area is a necessary part of the procedures for appropriate academic assessment of secondary students. Make sure that the steps in Appendix A have been carried out. Hammill and Bartel (1990) and Howell et al. (1993) offer assessment and intervention guidelines for social/emotional difficulties.

SUMMARY

There are numerous demands placed on students in secondary classrooms such as (a) bring necessary materials to class; (b) read from materials at or above grade level; (c) listen to lectures and take notes; (d) follow directions; (e) complete assignments; (f) work independently; (g) participate in discussion; (h) spell and write; (i) take tests; and (j) follow classroom rules. Problems with any of these demands can interfere with academic success. Therefore, academic assessment must be comprehensive, give recognition to all valued learning experience, be sensitive to process as well as products, and use a problem-solving approach to assessment — an approach that **I**dentifies and **De**fines the problem, **E**xplores alternative solutions, **A**cts on the plan, and **L**ooks at results (IDEAL).

Clarke, Clarke, and Lovitt's list of major uses for assessment information is appropriate for all levels of students and all academic areas as well as nonacademic areas:

- To improve instruction by identifying the specific sources of a student's error that requires remediation or the specific learning behaviors that might need to be encouraged and developed or discouraged and replaced.
- To improve instruction by identifying those instructional strategies that are most successful.
- To inform the pupil of identified strengths and weaknesses both in knowledge and in learning strategies so that the most effective strategies might be applied where most needed.
- To inform subsequent teachers of the student's competencies so that they can more readily adapt their instruction to the student's needs.
- To inform parents of their child's progress so that they can give more effective support. (Clarke, Clarke, & Lovitt, 1990, p. 199)

ANNOTATED BIBLIOGRAPHY

Choate, J. S., Enright, B. E., Miller, L. J., Poteet, J. A., & Rakes, T. A. (1992). *Curriculum-based assessment and programming* (2nd ed.). Boston: Allyn & Bacon.
The second edition of this book emphasizes the bond between curriculum-based assessment and curriculum-based programming. Step-by-step practical assessment and programming procedures are provided that will enable the assessor/interventionist to personalize instruction based on assessed needs. The appendices contain skill objectives and sample test items.

Howell, K. W., Fox, S. L., & Morehead, M. K. (1993). *Curriculum-based evaluation* (2nd ed.). Pacific Grove, CA: Brooks/Cole.
The basic concepts of evaluation and instruction are integrated with current research knowledge in order to generate productive tools for classroom use. Functional classroom-based evaluation is explained and demonstrated across academic, social, and task-related skills. Teaching recommendations are made for each of these skill areas.

Lesh, R., & Lamon, S. J. (Eds.). (1992). *Assessment of authentic performance in school mathematics.* Washington, DC: AAAS Press.
Most of the chapters in this book focus on clarifying and articulating the goals of assessment and instruction. The content of assessment is stressed vs. the mode of delivery. "Portfolio," "performance," "authentic," and other forms of assessment are viewed as means to an end, not as ends themselves.

Masters, L. F., Mori, B. A., & Mori, A. A.(1993). *Teaching secondary students with mild learning and behavior problems* (2nd ed.). Austin, TX: Pro-Ed.
This book is an excellent instructional resource. It covers assessment and evaluation of student progress; specific instructional methods, techniques, and materials for remedial, compensatory, tutorial, and strategic-oriented programs; vocational and transitional training; social skills training; and computer and technological classroom applications. It also contains checklists for instructional modifications and transition planning.

Takanishi, R. (Ed.). (1993). Adolescence [Special issue]. *American Psychologist, 48*(2), 85–201.
This issue highlights the knowledge base in specific areas of adolescent development, assesses the intervention experience, and attempts to strengthen the role of research and professional practice in the development of public policies. Article authors address how this period of great risks can be turned into opportunities for well-being.

Appendix A

Academic Assessment of Secondary-Age Students (7th–12th Grades)

I. The Screening Process

A. Indirect Student Assessment

1. Develop a brief rating form for sixth-grade teachers to complete that indicates students' current academic and behavioral adjustment and projected adjustment to junior high.
2. Check health records for current and past health information such as acute or chronic illness, frequent trips to the office for health complaints, and medication.
3. Check attendance records. Screening team determines standards for excessive absences. The files of any student demonstrating excessive absences will be reviewed.
4. Check the cumulative folder for current and past special services such as Chapter 1, resource help, counseling, speech and language, and the like.
5. Review grade reports. The files of any student failing one or more subjects will be reviewed.
6. Review standardized group test data. Screening team develops cut-off scores. The files of any student whose scores are below this will be reviewed.
7. Develop a checklist summary sheet that can be completed for all students identified during the screening process. Questions to be answered on the checklist include:
   a. Is there concern about academic skills or problems in specific content areas?
   b. Are there descriptive samples of behavior and work samples available?
   c. What is known about school-related and outside-of-school variables?
   d. What if any, intervention efforts have been attempted?
8. Ask for current information from teachers and parents about the students identified during the first stage of the screening process. Create your own checklist of questions to ask parents and teachers. Or use a checklist or survey already created such as the "General Teacher Survey" in Choate et al. (1992).

B. Direct Student Assessment

1. Administer a survey-level assessment instrument in any area where additional information is needed before proceeding with a specific level assessment such as self-esteem, study habits, skills, and strategies.
2. Interview the students identified during the first stage of the screening process.
3. Observe the students identified during the first stage of the screening process.

C. Interpret the Screening Data

1. Establish weighting for each piece of information gathered.
2. Establish the inclusion/exclusion criteria for proceeding with a specific level or personalized assessment and intervention.
3. Establish priorities based on significant need for intervention (**I**dentify the **P**roblem).

II. The Diagnostic Process

A. Determining Academic Expectations/Conducting Curriculum Analyses

1. Review district/school/teacher goals in the academic or content area.
2. Review textbook objectives, content, reading level, and so forth.
3. Review specific classroom requirements.
4. Check readability level of informal inventory and curriculum materials available.

B. Indirect Student Assessment
  1. Review classroom work.
  2. Check: reports from parents, teachers, school psychologists.
  3. Interview the student: conducted by classroom teacher or school psychologist.
  4. Perform curriculum-based assessment: conducted by classroom teacher, special teacher, or school psychologist.
  5. Do an informal analysis of responses — error pattern analysis, task analysis.
  6. Assess instructional environment.

C. Direct Student Assessment
  1. Check skill levels in the academic or content area.
    a. word recognition (sight vocabulary, phonetic analysis, structural analysis, word meaning)
    b. reading comprehension (literal, interpretive, critical, and words in context)
    c. mathematics (integration of mathematical knowledge, problem solving, communication, reasoning, mathematical concepts, mathematical procedures, mathematical disposition)
    d. written expression (mechanics, usage, ideation)
    e. spelling and handwriting
    f. science (vocabulary, problem solving)
    g. social studies (vocabulary, graphic aids)
  2. Check task-related skills/strategies.
    a. organization
    b. categorization
    c. alphabetizing
    d. directions
    e. book use
    f. references
    g. study habits
      1. outlines
      2. study strategies
      3. adjustment of reading rate
    h. test-taking skills
  3. Check vocational goals and skills.
    a. interest
    b. aptitude
    c. opportunities
  4. Check social skills.
    a. observation
    b. self-report or third-party report

BEST COPY AVAILABLE

III. The Intervention Process.

- A. Describe present level of performance (**D**efine the Problem).
- B. Set goals/priorities.
- C. Select content.
- D. Select methods and materials (**E**xplore Intervention Options).
- E. Program for subskills.
  1. Development strategies
  2. Corrective strategies
  3. Maintenance strategies
- F. **A**ct on the Plan.
- G. Evaluate effectiveness/Monitor progress (**L**ook at Results).
- H. Recycle if necessary.

Appendix B
Assessment of Word Recognition Skills

Known Information	Probable Causes	Assessment	Intervention
Oral reading is slow but accurate	Lack of practice in reading quickly	Ask student to reread passage	If rate increases work on improving rate
	Poor use of passage content	Same as above	Same as above
	Poor use of phonics; speed would increase errors	Analyze decoding errors	Teach the use of skills emphasizing rate
Oral reading is inaccurate	Not reading for accuracy	Tell student the purpose for reading and have student reread passage	Emphasizing reading for accuracy
	Poor use of context	Check the use of text	Emphasize accuracy; teach higher-level strategies
	Learned error patterns	Categorize decoding errors by strategy	Correct the error patterns
	Poor use of decoding	Categorize decoding errors by content	Teach the use of skills within passage reading

Best Practices in Assessment with Persons Who Have Severe or Profound Handicaps

Wendy K.Berg
University of Iowa

David P. Wacker
University of Iowa

Mark W. Steege
University of Southern Maine

OVERVIEW

Students who are severely to profoundly handicapped constitute a diverse group of individuals. The label *severely handicapped* is applied to students who display severe deficits in adaptive skills and may include students with moderate to profound mental retardation and those who have severe sensory or physical impairments. Within the past 10 years, the use of this label in public school programs has been expanded to include students with severe health impairments and students who engage in extreme forms of aberrant behavior such as self-injury. As a result, the label provides the practitioner with limited information regarding the student to be served.

The diversity of the students who are included by this label is exemplified by the variety of educational programs that serve this population. For example, within different school systems, students with severe disabilities may attend segregated schools, be taught in regular education classrooms with same-age nonhandicapped peers, or spend the majority of the school day in community-based programming. The majority of students with severe disabilities, however, are served in self-contained with integration classrooms located in regular public school programs. It is not unusual for the children in self-contained classrooms to represent an age span of several years, to range in speech skills from those who speak in brief sentences to those who display no expressive skills, and to range from those who are independent in all self-care skills to those who are dependent. Because of the variations in programming and the unique characteristics of each student, it is important for the school psychologist to become familiar with the student's classroom as well as with the student.

Regardless of the type or level of disability the student displays, the goal for education remains fairly constant. The student should be able to participate as independently as possible in activities that are typical of other students of the same chronological age. This goal reflects two standards for educational programs serving students with severe disabilities: (a) age-appropriate activities and (b) a continuum of partial participation to complete, independent participation in educational, social, and vocational activities.

The standard denoted by *age-appropriate* refers to providing the student with activities and materials that are typical of those engaged in by students of the same chronological age but who have not been diagnosed as having a disability. The second standard reflects the principle that independence in an activity is a goal, not a requirement for participation in classroom activities. Although some students may not be capable of performing every component of an activity, every student should be capable of performing at least some components. Allowing students to participate, with whatever level of assistance they require, is referred to as partial participation.

Classroom activities for students with severe disabilities should occur in settings with other students of the same age, who may or may not be disabled, with ample opportunities for social interactions and the formation of friendships. Attendance and participation in classrooms and activities with nonhandicapped students of the same chronological age is referred to as integration or inclusion. Inclusion for students with severe disabilities may range from participation in nonacademic class periods, such as music and art, to full inclusion as a student enrolled in a regular education classroom with same-age peers. The diagnosis of the student does not dictate the setting in which education is best provided.

Finally, the skills developed in the educational setting should build on the student's strengths and lead toward the opportunity for gainful employment

770

as an adult. The priority of any given educational goal in a student's individual education plan (IEP) depends on the age of the student and the wishes of the student and his or her parents. It is simply not possible to prioritize goals in an a priori fashion without conducting an individualized assessment.

The purpose of this chapter is to present some of the current methodologies available for conducting assessments and effective intervention procedures for students who are severely to profoundly disabled. Traditionally, the role of the school psychologist has been limited to assessing students' intellectual or developmental functioning and determining their eligibility for various special education programs. In this chapter we are proposing a different role: to assess the environmental conditions under which a student will be most successful in achieving individualized education goals within the educational setting of choice. Identifying the environmental conditions that promote optimal performance necessitates that the school psychologist observe the impact that different antecedent and consequence variables have on the student's ability or motivation to respond correctly to task directions or social cues. This is in contrast to determining if the student meets initial baseline criteria for participation in a specific educational program.

Thus, we are suggesting that participation be based on IEP goals, not on assessed abilities. When participation in a situation has been agreed on by the interdisciplinary team, the goal of assessment is to identify environmental conditions that facilitate success. This is not to suggest that we see no role for IQ or other forms of psychometric testing. As will be seen in one of the case examples, we believe that psychometric assessment can be a useful evaluation, but not as the only or primary form of assessment. Also, school psychologists tend to know much more about psychometric than behavioral assessment; therefore, we devote more space to assessment of environmental (antecedent and consequence) variables.

The procedures are presented in the context of three case examples (Table 1) illustrating issues you are likely to encounter while serving programs for students with severe/profound disabilities. The first example, Katie, is a referral for an evaluation of cognitive abilities and overall level of functioning. Katie is typical of many referrals in that she does not engage in many adaptive behaviors, nor does she communicate effectively; however, she is responsive to the people and activities in her environment. For Bill and Renee, the purpose of referral is to change the student's behavior. In Bill's case, assessment focuses on reducing the occurrence of head banging and increasing his participation in adaptive behaviors. The assessment designed for Renee focuses on identifying environmental factors that will increase her participation in classroom activities.

BASIC CONSIDERATIONS

Purpose of Assessment

The first step in any assessment is to determine the purpose of assessment from the perspectives of the parents, teachers, other educational staff, and, when appropriate, the student being evaluated. The involvement of parents and teachers in the assessment process is critical, because they provide valuable information regarding the history of the student, previous approaches to assessment and treatment, and the current goals for the student. For Katie, the referral question centers on identifying the most appropriate classroom placement for the next school year. For Bill, the reason for referral is to obtain an intervention procedure that will reduce or eliminate self-injury. For Renee, the goal is to improve work performance.

Each referral question requires collecting a different set of information to satisfactorily address the issues raised. The assessment question dictates the type of information that is needed and, therefore, the units of behavior to be examined. For example, Katie's assessment will focus on her performance on selected standardized tests to determine her level of intellectual functioning. Renee's teacher is not interested in evaluating her intellectual functioning but, rather, in identifying an intervention procedure that will result in better work habits. For Bill, assessment will focus initially on the frequency of his self-injurious behavior under different environmental conditions.

BEST PRACTICES

Diagnostic Assessment

Prior to conducting the evaluation, the school psychologist should first consult with parents, classroom teachers, and therapists to determine the student's most reliable means of communication (e.g., verbalization, signing, pointing to pictures, augmentative communication). Having identified the student's means of communication, the school psychologist then selects the assessment procedure that is matched to the student's style of communication. For example, with a student who evidences little, if any, verbal skills but who has a reliable reach-and-point response, the Peabody Picture Vocabulary Test–Revised or the Test of Nonverbal Intelligence might be used to estimate cognitive abilities. Similarly, preferred positioning and level of stamina are important considerations in conducting assessments with students who have significant physical disabilities or medical conditions. With these students, it is often helpful to ask the parent or classroom teacher to participate in the assessment to assist in determining the degree to which the student is attending and responding to the questions/test stimuli. Salvia and Ysseldyke (1988) and Sattler (1988) provide guidelines

TABLE 1
Case Descriptors and Assessment Approach

Student	Description	Referral Issue	Assessment Approach
1. Katie	A 3-year-old with multiple handicaps; has limited use of arms and legs; uses no formal communication. Appears to be attentive to activities and people in environment.	Most appropriate placement: adaptive skills, general level of functioning.	Intellectual and adaptive behavior assessment.
2. Bill	A 12-year-old diagnosed as profoundly mentally retarded; uses no formal communication system; has 10-year history of self-injurious behavior.	Decrease self-injurious behavior; increase participation in adaptive activities.	Functional analysis of behavior.
3. Renee	A 6-year old diagnosed as severely mentally retarded; communicates with 1–2 word statements; does not participate in assigned activities.	Increase participation in adaptive activities.	1. Reinforcer assessment. 2. Structural assessment of conditions promoting on-task behavior.

and information regarding the use of specific standardized assessments for persons with severe handicaps.

In most cases, the results of assessment of intellectual functioning for students with severe, multiple disabilities yields *global estimates* of cognitive functioning. Subtest analysis and hypotheses about cognitive strengths and weaknesses are rarely clinically significant. Adaptive behavior assessments, particularly curriculum-based assessments, will result in information that is useful to the interdisciplinary team for designing habilitative programs. (See chapter by Harrison and Robinson [this volume] for a thorough review of adaptive behavior assessment.)

In most cases, the results of adaptive behavior assessments also indicate significant deficits across a variety of domains (e.g., expressive language, domestic activity, personal living, vocational, leisure, social). However, global assessments are often an insensitive measure of the student's level of functioning with respect to specific but complex skills such as bedmaking, toothbrushing, laundering, meal preparation, operating a microcomputer, and so forth. A comprehensive analysis of the student's degree of mastery of these types of tasks needs to be individually tailored. For example, task analysis data could be collected to identify mastery or the level of assistance (type of prompts) that a student needs within and across tasks. By themselves, the results of norm-referenced adaptive behavior assessment, although useful in describing a student's current level of global functioning, are not particularly useful in prescribing individually designed habilitative programs.

Another method of describing a student's current level of functioning involves the use of a semistructured interview with parents, teachers, and others who provide services to the student. We suggest focusing the interview on the following: (a) behavioral assets (i.e., behaviors that the student performs independently or with minimal assistance), (b) behavioral deficits (i.e., behaviors that the student has not learned or mastered), (c) behavioral excesses (i.e., behaviors that are considered aberrant), (d) survey of reinforcers (e.g., types of activities, foods, and social attention that appear to be preferred by the student), (e) means of communicating wants and needs (e.g., signing, language board, verbalizations), and (f) primary concerns (i.e., behaviors to be targeted for skill development and, if any, behaviors targeted for elimination). The interview should be focused throughout on behaviors that are both functional and age-appropriate. This analysis not only yields information about the student's strengths and weaknesses, but also sets the stage for more comprehensive assessments.

In the case of Katie, the school psychologist consulted with family members and school personnel about her communication skills, positioning, and stamina. Given Katie's limitations with respect to verbal and motor abilities, the school psychologist administered the Peabody Picture Vocabulary Test–Revised. Katie accurately pointed to several pictures that corresponded to stimulus words presented by the school psychologist. Katie's performance was significantly below age level expectations, suggesting that she evidenced significant deficits in relation to one-word receptive language skills. The school psychologist next administered the American Association on Mental Retardation (AAMR) Adaptive Behavior Scale–School Version, with the classroom teacher serving as the informant. The results of adaptive behavior assessment suggested significant deficits across all domains. On the basis of this evaluation, the school psychologist offered the diagnosis of Mental Retardation, Severe. To further evaluate Katie's adaptive behavior skills, the school psychologist conducted a semistructured interview and identified several behavioral strengths, no maladaptive behaviors, and specific skills deficits.

Behavioral Assessment

Behavioral assessments are conducted to identify the conditions that guide and maintain a subject's behavior. The goal of assessment is to describe current behavior and identify effective interventions.

Behavior is always defined in a specific context, which is composed of both antecedents and consequences to behavior. Antecedent variables include contextual and instructional stimuli that precede or coincide with participation in targeted activities. Contextual variables typically include environmental stimuli such as the presence or absence of peers, noise, or other factors in the environment that might facilitate instruction or be distracting to the student. Among instructional stimuli are the manner in which the task is presented, such as one-to-one versus group instruction, the amount of work to be completed within one work session, and the presence or absence of prompts or cues to promote task performance.

Consequences are stimuli that follow a behavior. For example, *positive reinforcement* refers to what a student gains, such as tangible items, points, or praise; and *negative reinforcement* refers to what a student avoids or escapes, such as the assignment of additional work, ongoing task demands, or reprimands.

Defining and Measuring Behavior

Behavioral definitions describe the specific behavior a student exhibits in such a way that two or more individuals can agree that the target behavior has occurred. A behavioral definition is focused on the behavior displayed by a student and on the situation in which the behavior occurs, but not on the presumed causes or intent of the behavior.

When the behaviors of interest have been identified, the next step is to identify an observation system or instrument that will most accurately quantify the occurrence of these behaviors. For Renee, assessment will focus on determining the conditions under which she will actively and appropriately participate in classroom activities. In determining the conditions under which Renee will work most effectively, we are not interested so much in whether appropriate or inappropriate behavior occurs in a given situation, but rather in the relative frequencies with which the different behaviors occur across different types of activities and environmental manipulations. Similarly, the assessment for Bill will not focus on whether self-injury occurs during the school day, but rather on the relative frequency with which self-injury occurs across different antecedent and consequent conditions.

Time-based systems. Several different dimensions of behavior can be measured, but it is most common to measure behavior in terms of its frequency or duration. Frequency, how often the target behavior occurs, involves the use of event or interval recording. With event and interval recording systems, the student is observed for a fixed amount of time (e.g., 5–30 minutes) across observation sessions (Kazdin, 1982). Event recording consists of scoring each time the behavior occurs within that time period. Because the observer counts how often the target behavior occurs, the behavior must be a discrete event with a clear beginning and ending (e.g., Bill's striking his head against a table). If the behavior is not discrete, an interval recording system might be used. With an interval recording system, the time period is further divided into fixed intervals that range from seconds to minutes. In general, the smaller the interval the better. We often use a 6-second interval because 100 intervals occur in 10 minutes, which makes computations of percentages easy. The occurrence or nonoccurrence of the target behaviors is then recorded within each interval, with "percentage of intervals" being the outcome of interest. Duration recording measures the time that elapses from the onset of the response until the response ends. Unlike repetitive, discrete behaviors, which can be measured easily by event recording, the behaviors that are most appropriate for duration recording can be broadly considered as measures of persistence. The duration of a student's hand biting, for example, could be recorded with a stopwatch. This requires defining a certain unit of time (e.g., 5 seconds) that separates the occurrence of one behavior from the next.

The selection of event, interval, or duration recording is based on the occurrence of behavior and the purposes of instruction. Event recording is useful for high-frequency behaviors that are discrete. Interval recording is useful for high-frequency behaviors that are not discrete or when multiple behaviors are occurring. Duration recording is preferred when the time spent in a behavior or activity is important or when low-frequency responses persist for extended time periods.

Task analysis. In some cases, the question of interest revolves around how accurately or how completely a student performs tasks or activities. Task analysis data provide a direct assessment of these measures. With tasks analysis measures, a given task or assignment is divided into the component behaviors required to complete each part of the task. These

Repeat Steps 9 and 10 until silverware tub is empty.

Number of knives sorted correctly: ________/________ Total number of knives.
Number of spoons sorted correctly: ________/________ Total number of spoons.
Number of forks sorted correctly: ________/________ Total number of forks.

components are referred to as steps in the task analysis, and the student is scored on his or her performance for each task step. An example of a task analysis for sorting silverware is provided in Table 2.

For each step, the student is given a score of either + (completed the step correctly) or – (did not complete the step correctly). By dividing the total number of steps in the task analysis by the number of + scores, one can determine the percentage of the task or activity that the student performed correctly.

An alternative method for scoring performance by a task analysis is to indicate the level of assistance the student requires to complete each task step correctly. Assistance may range from no assistance to complete physical guidance (i.e., hand-over-hand guidance). A number or letter can be assigned for each level of assistance, and this score replaces the score of + or – for each step of the task analysis. Progress is measured by documenting the student's movement from more to less restrictive levels of prompting (Steege, Wacker, & McMahon, 1987).

Task analysis data are particularly useful in educational settings because they provide information regarding the types of errors the student makes as well as a score for overall accuracy. For example, by reviewing the student's performance on a silverware sorting task, you can determine if the student has difficulty in starting the task but performs well once started, or if the student has difficulty in sorting throughout the entire work period. Task analysis data are also useful for determining if poor performance is due to a lack of skills or a lack of motivation. If a student attempts to perform most of the steps in a task analysis but performs these steps incorrectly, a skill deficit is indicated. On the other hand, if the student does not even attempt to perform the assigned tasks, the problem may be one of motivation instead of, or in addition to, a skill deficit. In these cases, assessment needs to focus on identifying positive reinforcers to be provided to the student contingent on task performance.

Assessment Procedures

Hypothesis formulation. For students such as Bill and Renee, the purpose of assessment is to identify specific interventions to change their behavior. Depending on the referral question, the primary goal of assessment may be either to increase the frequency of a low-rate appropriate behavior, such as Renee's engagement in classroom activities, or to decrease the occurrence of a high-rate aberrant behavior, such as Bill's head banging. When the referral question centers on a low-rate response, such as the lack of a desired behavior, task analysis and reinforcer assessment data may provide the most useful information. When high-rate problematic behavior is the issue, assessment should focus on identifying, by a functional analysis, the variables in the school environment that are maintaining the behavior (Iwata, Dorsey, Slifer, Bauman, & Richman, 1982).

In order to increase or decrease the frequency of any behavior, you need to know what environmental factors influence the occurrence of the behavior. For example, Renee's completion of classroom activities might be affected by the presence or absence of peers and by the amount of the teachers' attention she receives, but the type of activity assigned might not have any observable effect on her behavior. Because the number of environmental variables that may influence behavior is unlimited, you will need to de-

TABLE 3
Classroom Observation of Renee's Task Performance

Task	Conditions	% Task Step Completed	% Task Steps Completed Independently
Brush teeth	1:1 Teacher assistance with no peers	70	65

velop specific hypotheses to guide your assessment efforts (Repp, Felce, & Barton, 1988).

Hypotheses can be based on information obtained through interviews with the parents and teachers, or through direct observation of students across different situations. We recommend a combination of the two procedures. Interviewing the people who have frequent, direct contact with the students will provide information regarding the situations in which the behaviors of concern are most likely to occur as well as the parents' and teachers' perspectives on why the children behave the way they do. Direct observation of the children across different classroom activities will allow you to form your own hypotheses and to refine those developed from parent and teacher interviews. Table 3 provides an example of what an initial classroom observation might reveal regarding Renee's task performance.

Hypothesis testing. After a hypothesis is developed regarding the factors that influence a student's behavior, the next step is to directly test that hypothesis. To evaluate the effects that a given variable has on a student's behavior, observe the student across situations in which the hypothesized variable is present and situations in which it is absent. If the variable influences behavior, behavior will change reliably as the variable is introduced and removed.

There are at least three assessment procedures for testing hypotheses regarding the role of different environmental variables on a student's behavior. The first procedure, reinforcement assessment, focuses on identifying positive reinforcers that the student is willing to work for. Such an approach is useful for identifying consequences that would increase Renee's motivation to perform assigned activities. The second approach, functional analysis of consequences, provides a means for evaluating the effects that positive and negative reinforcers have on a student's behavior. This approach is typically reserved for aberrant behavior that occurs at high frequencies; it would be an effective assessment procedure for addressing Bill's head banging. The final procedure, functional analysis of antecedents, is used to evaluate the impact of different antecedent stimuli. This approach would provide another method for obtaining information regarding the impact of different environmental stimuli on either Renee's or Bill's behavior.

Reinforcer assessment. Reinforcer assessments are based on the operant principle that a reinforcer is something that increases the frequency of the behavior that it follows. In the case of Renee, the purpose of a reinforcer assessment is to identify consequences to behavior that Renee is willing to work for. In Renee's case, provision of the desired consequences is to be contingent on participation in classroom activities.

A reinforcer assessment begins with developing hypotheses, which in this case involve identifying activities, toys, food items, and social consequences, such as conversation, that Renee not only likes, but is willing to work to earn. From interviews of Renee's teacher and parents a list of potential reinforcers is identified, and the items are presented to Renee contingent on a desired response. By comparing the frequencies with which Renee engages in the desired response across different consequences, you can determine which consequences are positive reinforcers for Renee.

There are numerous methods for conducting reinforcer assessments. The procedure that we have found to be the most effective for students with severe to profound handicaps is a forced-choice procedure developed by Fisher et al. (1992). The assessment is conducted in two phases and begins with the identification of potential reinforcers. Typically, five to six items that are available in the classroom and that can be provided immediately following brief instances of a desired response are sufficient.

TABLE 4
Results of a Reinforcer Assessment for Renee

Phase 1: Activity/item offered	**% of offers in which item was selected**
Praise	85
High-5 hand shake	80
Juice	25
Sticker	25
Book	10
Phase 2: Consequences for completing task steps	**% of task steps completed**
Praise	92
Book	6
No consequence	18

At the beginning of each assessment session for Phase 1, the students are provided with a brief sample of each potential reinforcer. For example, if the list includes music, students are shown a radio and allowed to listen to music for 5–10 seconds. Similarly, for consumable items, such as graham crackers and juice, they receive a small bite or drink of the item. The purpose of sampling the items is to present the options and to familiarize the students with the symbol (usually the item itself) used to represent each option. After the students briefly sample each item, the formal assessment begins.

During Phase 1, the potential reinforcers are presented two at a time to the students, who are given 5 seconds to choose one of the items. Depending on their respective abilities, they indicate a selection by taking the item from the examiner's hand, reaching, pointing, or leaning towards or gazing at the item. When an item is selected, the students receive a sample of the item (e.g., a small bite, brief access to an activity, or several seconds of interaction). When the item has been consumed or the specified time elapses, another choice of two items is offered. A student who does not select either option within 5–10 seconds loses that choice and another set of two options is presented. Thus, it is critical that a choice response be within a student's repertoire.

Each item identified as a potential reinforcer should be paired at least one time with each of the other options. Also, the position of each item should be randomized across right and left locations to control for a position bias on the part of the student. Furthermore, the assessment should be repeated at least two or three times on different days to determine the stability of students' preferences. By comparing the frequency with which students select each item across assessment sessions, you can achieve a ranking of most preferred (most frequently chosen) to least preferred (least frequently chosen) items (see Table 4).

Identifying items that a student appears to prefer completes the first phase of this assessment. Then it is necessary to determine if the preferred item will serve as a reinforcer for the desired behavior. In Renee's case, the desired behavior is participation in class activities. To complete this second phase, Renee is provided with an activity to complete for 10 minutes. During that 10-minute period, Renee receives a brief sample of the most preferred stimuli (based on Phase 1) upon the completion of each step of the task analysis, following the least restrictive level of prompting that she requires for accurate performance. Her performance of task steps completed during this condition is compared with a similar 10-minute session in which she receives one of the least preferred stimuli for completing each task step, or in which she works without receiving any consequence for completing task steps.

Each of the conditions is presented in a counterbalanced order at least three times across at least 2 days. If Renee consistently completes more task steps when she receives the consequence identified as most preferred, then that stimulus is identified as a positive reinforcer for Renee and can be used for intervention. If Renee performs similarly across both consequences, then a reinforcer has not necessarily been identified. Remember, preference does not equal reinforcer. Phase 2 must continue with additional stimuli until (hopefully) a reinforcer is identified.

If time on task is of more interest than task completion or accuracy of performance, then an interval recording system can be used to measure the percentage of intervals in which Renee remains on task during the 10-minute assessment sessions. A comparison is made of the percentage of intervals in which

TABLE 5
Behavioral Assessment Protocols for Assessment of Self-Injurious Behavior (SIB) by Functional Analysis of Consequences

Condition	Task Setup	Activity	Contingency
Alone, no task	None	None	None
Alone, with task	None	Recreation; leisure task.	None
Demand	Psychologist presents instructional demands; ignores appropriate behavior.	Training in educational task.	Psychologist provides brief time-out from task contingent on SIB.
Social attention	Psychologist in room; ignores appropriate behavior.	Recreation; leisure task.	Psychologist provides social attention ("Don't do that; you'll hurt yourself") contingent on SIB.
Tangible	Psychologist in room; ignores appropriate behavior.	None	Psychologist presents preferred toys, objects, etc., contingent on SIB.

Note: Conditions based on Iwata, Dorsey, Slifer, Bauman, & Richman (1982) and Carr & Durand (1985).

Renee engages in on-task behavior across the different consequence conditions.

Functional analysis of consequences. Functional analysis is a special form of assessment reinforcer that is typically used to address aberrant behaviors that occur at a high frequency. As with other forms of reinforcer assessment, functional analysis is conducted by manipulating the consequences of behavior. However, it serves to identify what currently maintains an undesired behavior rather than what will increase an adaptive behavior. The basic premise of this type of assessment is that the behavior serves a function: to obtain the specified consequence. By systematically providing and withholding specific consequences for a problematic behavior across different conditions and comparing changes in the frequency of the behavior across sessions, we can determine which consequences result in the highest frequency of the behavior.

The consequences that are manipulated in a functional analysis represent different outcomes the child might experience as a result of aberrant behavior. For example, the consequences of Bill's head banging, although quite varied, can be divided among three general categories: (a) those that result in the gain of a desired outcome, such as social attention, a preferred toy, or a desired activity (positive reinforcement); (b) those that result in the removal of something not desired, such as physical contact or task-related demands (negative reinforcement); and (c) those that are not socially mediated but, rather, are maintained by intrinsic variables (automatic reinforcement) (see Table 5). By identifying the consequence that results in the highest frequency of the behavior, we can determine what is reinforcing (or maintaining) the behavior.

The first step in a functional analysis is the same as with reinforcer assessments: formulation of hypotheses about what is maintaining the behavior. When a hypothesis is formulated, the next step is to determine how to assess it directly. For example, if Bill's teacher notes that head banging occurs primarily during times of one-to-one instruction such as grooming tasks, it might be hypothesized that escape from task (negative reinforcement) is the maintaining event for head banging.

This hypothesis can be tested directly by engaging Bill in a grooming task. Each time he attempts to bang his head against the counter, his teacher might back away from him and remove the grooming materials. After a pause of 20–30 seconds, the teacher resumes the grooming task. The withdrawal from the activity described above is repeated each time head banging reoccurs. This analogue condition can be alternated with one in which attention is provided (e.g., "Don't do that, you'll hurt yourself") *only* when Bill engages in self-injury. That is, the teacher ignores Bill until Bill bangs his head.

Assessment involves recording the occurrence and nonoccurrence of Bill's self-injurious (head banging) and appropriate (task-directed) behaviors by either an event or an interval recording system across a fixed amount of time (e.g., 10-minute sessions). From repeating each of the analogue conditions at least twice and comparing the rates of self-injury across conditions, the maintaining conditions of Bill's self-injury may become apparent. If self-injury occurs more often during the condition in which all demands and task materials are removed, the assessment supports the hypothesis that escape from task demands serves as a reinforcer for head banging. By alternating the escape with the attention condition and recording each occurrence of self-injury, we have met the two criteria for a functional analysis: direct observation and experimental control. In this case, experimental control is demonstrated through an alternating treatments design. (See chapter by Keith [this volume] for a description of single-case designs.)

Functional analysis of antecedent stimuli: Structural analysis. The final approach to evaluating the role of different environmental stimuli on a student's behavior is to conduct a functional analysis that manipulates the antecedent stimuli rather than the consequences (Carr & Durand, 1985). For the purposes of this discussion, we refer to this assessment as a structural assessment, because it focuses on the effects of the structural or contextual variables on behavior. A structural analysis requires that we observe the behavior under different environmental conditions. For example, we can observe behavior as it occurs naturally in the classroom. We can observe Renee's behavior under the natural classroom conditions and compare her rate of on-task behavior during individual versus group work periods so as to evaluate the effects of having peers in close proximity to her. We could also observe behavior across preferred and nonpreferred tasks to determine if task preference affects behavior.

When we observe different frequencies of behavior across different situations or activities, we can develop hypotheses regarding which variables account for those differences. If we observe that Renee remains on task for 80% of the intervals during group projects but only 20% of the intervals for independent work, we might hypothesize that Renee prefers working within a group rather than working alone.

Although the presence of peers is one variable that might be associated with different frequencies of on-task behavior, there are other factors that might confound the results of our assessment. It is plausible, for example, that different types of tasks are associated with individual versus group activities. Furthermore, group and independent activities might be associated with different amounts of attention from teachers as well as peers.

To test the roles of the different variables that might be influencing Renee's behavior, we could set up conditions either within or outside the classroom to look at very specific relationships between the presence or absence of different antecedent stimuli and the occurrence of on-task behavior. We can test the role of peer presence, for example, by comparing Renee's behavior across two different conditions — having her work on a task at a table with and without peers — in neither condition receiving the teacher's attention. Thus, the activity and amount of teacher attention are held constant across the two assessment conditions that directly vary the amount of peer attention. If differences in behavior occur reliably across the two conditions, the role of peers as a variable associated with high rates of on-task behavior is confirmed. In addition, the influence of peers is assessed without having to instruct them on how to behave, as would be needed in a functional analysis.

Each type of assessment presented in this section is conducted prior to intervention to help us identify which interventions might be most useful. The results of assessment permit us to match intervention to the specific environmental conditions guiding a student's behavior.

Matching Intervention to Assessment

The primary purpose of assessment is to provide guidance for ongoing instruction. When the initial assessment is completed, it is possible to begin intervention immediately, because the results of assessment constitute the first phase of intervention. The following examples of Renee and Bill demonstrate how the assessment data can be translated directly into ongoing instruction. Notice how many options arise for different types of treatment.

Use of reinforcer assessment data for Renee. The goal of assessment for Renee is to increase her participation in assigned classroom activities. The results obtained from the reinforcer assessment provide two sets of information that can be used to develop an intervention plan. First, the results of the assessment identify a reinforcer, or perhaps several reinforcers, that can be used to increase the amount of time Renee spends engaged in classroom activities. The stimuli that result in the highest frequency of on-task behavior (i.e., praise) or the highest accuracy in performance can be provided to Renee contingent on participation in the assigned activity.

Intervention begins by placing Renee in the context of an assigned activity. As soon as Renee complies with a teacher request or participates in the activity for a specified amount of time, she receives the reinforcer. After the reinforcer is consumed or after a brief amount of time (up to 1 or 2 minutes), Renee is returned to the task and allowed another opportunity to earn the reinforcer. Over time, and with ongoing success, the amount of time required of Renee before she receives reinforcement can be increased slightly.

The second set of information derived from a reinforcer assessment is a list of consequences that Renee will not work for; that may, in fact, be aversive to her and function as punishers! For example, it is not unusual for an item listed initially (e.g., books) as a potential reinforcer to result in lower frequencies of target behavior than when no consequence is provided. In short, that consequence is inhibiting performance and is, therefore, punishing. Thus, a reinforcer assessment can also help you avoid the inadvertent use of punishment.

If a student is suddenly or unexpectedly performing poorly, it may be helpful to evaluate the effects of the stimuli that typically follow the completion of the target task to determine if that activity is preferred or nonpreferred. For instance, the teacher may typically send students back to their desks to play quietly or look at books when they've completed their assigned task. If Renee prefers to be with the teacher, she is in effect being given a choice between (a) completing her work and leaving the teacher to return to her desk (i.e., punished for working), or (b) dawdling over her work and remaining in the presence of the teacher (i.e., reinforced for remaining off-task). In fact, if Renee remains off-task long enough, she may gain one-to-one instruction with the teacher.

Use of structural assessment results for Renee. The results of the structural assessment provide information that can be used to augment an intervention based on another form of assessment (e.g., reinforcer assessment or functional analysis) or to develop a separate intervention. In Renee's case, the results of the structural assessment can be used to arrange assigned activities in such a way that the likelihood of participation is maximized.

If the results of the structural assessment indicate that Renee performs better within a peer group than at her seat, two options are available. First, the reinforcement program can be implemented only during times in which Renee is required to work at her seat. In this scenario, the reinforcer is used to compensate for the differences in the two task arrangements. This option would be a logical intervention if Renee's off-task behavior occurs primarily during seatwork.

A second option is to implement the reinforcement program within group activities to maximize the likelihood that Renee experiences the reinforcer. During the initial stages of this intervention, seatwork is minimized. After Renee consistently participates in the group activities for an acceptable amount of time, the reinforcement program is transferred to seatwork. Renee's success with the program in group settings may generalize to the seatwork situation. This is a logical intervention if Renee's off-task behavior occurs across both group work and seatwork.

A third option of incorporating the reinforcement program across both types of activities may appear attractive. However, such an extensive program is likely to be too cumbersome to be implemented with good integrity. Whenever a choice must be made between good integrity and increased frequency of treatment sessions, select the option that promotes good integrity.

Structural assessments can be used to develop interventions that are separate from other assessments. For example, Renee's teacher can structure the classroom routine so that tasks that are less preferred by Renee, but which must be completed, are presented in group situations. Alternatively, group activities might be used as warm-ups for independent seatwork. With a warm-up, Renee starts out working within a group but then is required to work at her seat for the remaining time. Seatwork is then followed (reinforced) by more group activity. As Renee's performance improves, the amount of time spent in seatwork is increased in proportion to the amount of time spent in group work until an acceptable balance between the two types of activities is achieved.

Use of functional analysis results for Bill. The results of the functional analysis demonstrate that Bill's head banging is maintained by negative reinforcement; that is, Bill bangs his head to escape from task demands. Thus, when Bill is provided with a demanding task such as grooming, he bangs his head against a counter, which results in time-out (removal from the grooming area). Given these findings, at least three intervention strategies are possible, depending on their acceptability to the IEP team and parents: (a) providing Bill with only nondemanding or preferred tasks, which requires a complete restructuring of his education program and the development of a plan to reintroduce demanding tasks; (b) providing him with brief "work breaks" that are contingent on appropriate behavior; or (c) teaching him to sign "stop" or "break" to indicate that he wants a brief break and providing a break for this appropriate communicative response (Durand & Carr, 1985). With each intervention plan, time-out must be stopped; Bill must not be allowed a break from the task when self-injury occurs. In fact, if Bill continues to gain a break from task (e.g., in the form of time-out) for head banging, then head banging will be reinforced, and you can expect Bill to continue to engage in self-injury.

Evaluation intervention. Each intervention is based directly on the results of assessment. The outcomes of intervention will ultimately confirm the validity of the assessment. For this reason, when intervention is first initiated, there is a need to develop an ongoing evaluation plan that teachers and parents can use to monitor the progress of the student. (See chapter by Tilly & Flugham [this volume] for a description of evaluation.) For both Renee and Bill, the goal of intervention is that they will participate in the desired tasks in the selected environment with as little intrusion as possible. If intervention is successful, Renee and Bill will be able to perform assigned activities under the same conditions as the other students in the classroom or perhaps as students in a less restrictive classroom placement. Thus, any components of an intervention that add to the classroom routine should be restricted to those that are essential.

For Renee, this could be accomplished by periodically probing her performance across group work and seatwork when additional reinforcement for participation is not provided. With Bill, regardless of the intervention plan selected, intervention will ultimately involve requiring Bill to participate in demanding activities for increasing amounts of time or until set amounts of work are completed. Probing Bill's performance to these ultimate criteria will make it possible to adjust the intervention protocol to facilitate acquisition of that goal. Evaluating the effectiveness of an intervention is discussed in the chapter by Tilly and Flugham (this volume).

SUMMARY

Most commonly, school psychologists have their first contact with students who are severely handicapped when they conduct some type of assessment. It is critical that the primary purpose of assessment be identified and discussed with the parents and IEP team. Assessment can be conducted to describe current functioning, to predict future functioning, or to prescribe intervention plans. Each type of assessment approach leads to different assessment strategies and outcomes. The approach selected should be based on the reason for referral, previous assessment results, and ultimately on the instructional goals for the student.

Assessment and intervention of students diagnosed as severely handicapped might be best conceptualized as constituting a continuum, ranging from initial assessment that prepares for direct intervention to ongoing evaluation of intervention that leads to documentation of improvement or changes in the intervention plan. Even when placement is the major outcome, assessment and intervention are driven by the educational goals developed for the student and by hypotheses developed about the student's responding in certain conditions. The initial assessment results serve to confirm or refute these hypotheses. If confirmed, intervention is initiated that serves to further substantiate original hypotheses or to modify initial conclusions. If refuted, further assessment may be needed. In either case, assessment is the first step of intervention. Ultimately, the outcomes of intervention provide the final analysis of assessment.

Singh (Eds.), *Nonaversive and aversive interventions for persons with developmental disabilities* (pp. 301–330). Sycamore: Sycamore.
As the title implies, this chapter presents a thorough discussion of both the conceptual and applied issues related to the use of functional analysis procedures. The chapter begins with a discussion of the rationale for using functional analysis, followed by a complete description of the assessment procedure including options for data collection. Guidelines are provided regarding the interpretation of assessment results and development of interventions. In addition, the authors discuss possible confounding factors and limitations to the procedure.

Berg, W. K., & Wacker, D. P. (1991). The assessment and evaluation of reinforcers for individuals with severe mental handicap. In B. Remington (Ed.), *The challenge of severe mental handicap* (pp. 25–45). London: John Wiley & Sons Ltd.
This chapter provides an overview of a variety of reinforcer assessment procedures that have been successfully applied to persons with severe mental disabilities. Issues related to identifying reinforcers for persons with severe disabilities are discussed. Appropriate reinforcer assessment procedures are described and a discussion of their applications to educational settings is provided. The reinforcer assessment procedures are presented in the framework of those appropriate for low-rate behavior and those appropriate for high-rate behavior.

Fisher, W., Piazza, C., Bowman, L., Hagopian, L., Owens, J., & Slevin, I. (1992). A comparison of two approaches for identifying reinforcers for persons with severe and profound disabilities. *Journal of Applied Behavior Analysis, 25,* 491-498.
A forced-choice reinforcer assessment procedure is compared with one developed by Pace, Ivancic, Edwards, Iwata, and Page (1985). Prior to this article, the procedure developed by Pace et al. served as the standard for reinforcer assessments for persons with severe disabilities. Fisher et al. discuss the limitations of the Pace et al. procedures and present the forced-choice procedure as an alternative approach for identifying reinforcers. We consider the forced-choice approach to be a best practice for identifying reinforcers for persons with severe disabilities.

Repp, A., Felce, D., & Barton, L. (1988). Basing the treatment of stereotypic and self-injurious behaviors on hypotheses of their causes. *Journal of Applied Behavior Analysis, 21,* 218–289.
In this article, the process of developing and testing hypotheses regarding the cause of maladaptive behaviors is presented and discussed. Experimental analyses demonstrating the effectiveness of this approach are presented for three subjects.

Rusch, F., Rose, T., & Greenwood, C. (1988). *Introduction to behavior analysis in special education.* Englewood Cliffs, NJ: Prentice-Hall.

This book describes an alliance between special education and applied behavior analysis, reviews the practical and conceptual issues relative to behavior assessment and intervention with special education populations, and describes the application of behavior analysis to adaptive and maladaptive behaviors. The chapter describing the use of single-case designs to evaluate student progress is very useful.

Best Practices in the Assessment of Children with Attention Disorders

Steven Landau
Illinois State University

Barbara G. Burcham
University of Kentucky

OVERVIEW

Most school psychologists are already quite familiar with children who have deficits in attention, and this disorder by whatever name, is easy to conceptualize. Unfortunately, efforts at consistent communication have been more elusive. Historically, the disorder has been known as "brain damage syndrome," "minimal brain dysfunction," "hyperkinetic reaction to childhood" (i.e., hyperactivity), "attention deficit disorder" (with and without hyperactivity; ADD), and "attention-deficit hyperactivity disorder." Although frustrating for some, this trend of changing nomenclature does represent improved understanding of the population of children with ADHD (Schaughency & Rothlind, 1991).[1]

Children with attention deficits belong to a relatively large male-dominated group (prevalence estimates suggest about 5% of school-age children) who have serious difficulties in concentrating, inhibiting inappropriate responses, and getting along in the everyday world (Whalen, 1989). Therefore, their presenting problems clearly put them at great risk for difficulties at school, in terms of both academic performance and interactions with adults and peers. Thus, the school psychologist may be in a better position than any other professional to conduct a comprehensive assessment of the child with ADHD.

However, school psychologists are faced with the arduous task of reconciling confused communication among parents, medical and mental health clinicians, and school personnel due to discrepant classification models. Family physicians, pediatricians, psychiatrists, and all other mental health professionals use the psychiatric taxonomy found in the *Diagnostic and Statistical Manual of Mental Disorders* for the purpose of labeling. In contrast, classification by school personnel is the product of legal mandate, such as the reauthorized Public Law 94-142 (now the Individuals with Disabilities Education Act). Thus, school-based assessment of children with attentional difficulties should not be undertaken to address the diagnostic criteria for ADHD. Instead, the assessment objective for school psychologists is to determine the extent to which attentional problems are interfering with the child's academic, affective, and social needs, such that an appropriate intervention plan can be developed.

BASIC CONSIDERATIONS

Primary Characteristics of the Disorder

The evolving terminology characterizing children with attention deficits indicates a shift in emphasis regarding what is considered most central to the disorder. Most researchers agree that a deficit in *sustained attention*, the inability to remain vigilant, represents a significant difficulty for the child with ADHD (Douglas, 1983). Thus, these children appear much less persistent than their classmates. Even though many teachers use the term "distractible" to characterize their observations of a student's school performance, distractibility implies that the child seems unable to focus on task-relevant stimuli. It would seem that some students' attentions are seduced by extraneous and irrelevant events more aptly termed *selective attention deficit*. However, the bulk of current research indicates that their greatest difficulty stems from an inability to sustain a response long enough to accomplish assigned tasks. Thus, they lack perseverance in their efforts. As a consequence, parents and teachers attribute to them characterizations such as "doesn't seem to listen," "fails to finish assigned tasks," "can't concentrate," "can't work independently of supervision," "requires more redirection," and "confused or seems to be in a fog" — all apparently the result of this inability to sustain attention (Barkley, 1990).

However, it is important to stress that, even though inattention may be the source of some difficulty in a less structured, free-play setting, it is the more restrictive academic setting that creates the greatest problem for these youngsters (Milich, Loney,

782

& Landau, 1982). Thus, the specific expectations within a setting, and its relative degree of structure, play an important role in determining how truly deviant the child with an attention deficit might actually be. This may explain, in part, why limited correspondence exists when parents and teachers rate the symptoms of these children (Achenbach, McConaughy, & Howell, 1987). Expectations in the home environment are clearly quite different from those at school. This point was recently reinforced in a study by Landau, Lorch, and Milich (1992), who were intrigued by the surprising but frequent anecdote from parents that their child with ADHD is able to attend to television (for example, "He sits glued to the TV for hours!"). In fact, a pediatrician's recent advice column in *Parents* magazine suggested to parents that they could rule out thoughts of ADHD if their youngster was able to pay attention to television. Results of the Landau et al. study indicated that boys with an ADHD diagnosis, who are known to be extremely inattentive in the classroom, were able to attend to educational television to an extremely high degree and were indistinguishable from normal age-mates under some conditions. It seems evident that television holds greater intrinsic appeal than academic work for the child with ADHD and does not represent the historical source of frustration and failure associated with the classrooms. Thus, the Landau et al. (1992) study highlights the notion that measures of attention must be evaluated in terms of their ecological validity; that is, the nature of the task, and the assessment setting, must be representative of the criterion being predicted. As such, one would not necessarily expect measures of attention in the laboratory to correspond with attentional performance in the classroom.

The second primary symptom, *impulsivity*, involves behavioral disinhibition (Barkley, 1990) or problems with inhibitory control. As with inattention, impulsivity is a multidimensional construct, and it can be defined in several ways (Olson, 1989). For example, children with attention deficits can be impulsive in their problem solving when confronted with academic tasks. They are extremely quick to issue a response without considering or scanning all response alternatives. As such, they become known as fast but careless and inaccurate problem solvers. Obviously, this failure to engage a more reflective response style can have a deleterious influence on the child's academic achievement.

Unfortunately, impulsive responding, when considered as a manifestation of cognitive tempo, is extremely difficult to operationalize and quantify with objective methods. Even though laboratory procedures have been developed to evaluate this impulsive response style, empirical evidence for its construct validity is lacking (Milich & Kramer, 1984). In fact, performance on one laboratory measure frequently does not correspond with performance on another.

Besides cognitive tempo, impulse control problems can also manifest as an inability to suppress inappropriate behavior (also known as behavioral disinhibition). As such, children with attention deficits can be high risk takers (e.g., running out in traffic) and may be unable to delay gratification. In school, they experience difficulty waiting their turn in line, blurt out answers in class, constantly touch other children, and tend to be undesirable playmates because of their difficulty with turn-taking, sharing, cooperation, and a low tolerance for frustration while playing games (Landau & Moore, 1991). Here, too, problems exist regarding the clarity of the impulsivity construct, and there has been much debate regarding the central importance of this symptom. However, recent laboratory advances developed by Newman and Wallace (1993) to investigate behavioral disinhibition seem to offer an intriguing explanation for the difficulties experienced by children with ADHD (see Milich, Hartung, Martin, & Haigler, in press).

Finally, there is little controversy that many children with attention deficits engage in high-energy motor excess or *overactivity*. As with the other symptoms, overactivity can take many forms but is especially apparent as excessive body movements (both major and minor motor) and vocalizations. Thus, for example, these children are described as "always on the go," "squirmy and fidgety," "can't sit still," "hums and makes other odd noises," "talks incessantly," and "climbs excessively" (Barkley, 1990). When children with ADHD attempt academic seatwork, they may constantly get up and down from the desk (or do all seatwork while standing). In addition, many show minor motor fidgeting, such as pencil tapping or leg shaking, and seem unable to keep their hands off objects unrelated to the task before them. During individual psychological testing, children with attention deficits can be extremely challenging subjects, as they stand during testing or, if they do remain seated, rock the chair back and forth until it falls over. In addition, they may strive to handle the school psychologist's test materials throughout the evaluation, thereby disrupting all attempts at a standardized administration. However, the presence or absence of these behaviors during testing is not diagnostic in itself. It is critical to realize that children with ADHD may, or may not, be symptomatic during an office evaluation — be it during psychoeducational testing or a visit to the physician considering medication for the child.

Lastly, these children are often overactive and incessantly talkative in the context of social play — behaviors that can have a negative effect on peer relations (Landau & Moore, 1991). However, from an assessment perspective, it is important to remember that setting demands — in particular, the degree of structure in the environment — can influence the extent to which these children are considered deviant (Jacob, O'Leary, & Rosenblad, 1978). Thus, in a highly structured academic setting, where desks are placed in rows and all work is to be accomplished in one's seat, the child who is overactive may be considered extremely troublesome. In contrast, the same motor excess may be more tolerable in the open classroom setting, where cooperative learning is encouraged and students are expected to move about and collaborate with their classmates.

Associated Features

Children with attention deficits may experience numerous difficulties that go beyond the primary symptoms and diagnostic criteria. However, it is important to note that not all children with attentional disturbance experience these additional difficulties. This fact may account for the extreme heterogeneity among children who have received an ADHD diagnosis.

The most obvious secondary characteristic is conduct disorder, and many children with ADHD meet the special education eligibility criteria for Seriously Emotionally Disturbed (SED). Although the rates of overlap vary across studies, most investigators agree that up to one-half of all children with ADHD are comorbid for conduct disorder and/or oppositional-defiant disorder. Thus, many may be extremely stubborn, noncompliant, and hostile, and engage in rule violations, stealing, lying, and aggressive acts (Hinshaw, 1987). Follow-up studies of children with ADHD indicate that those who also show conduct disorder not only are more difficult to manage as children but will also have more serious adolescent and adult adjustment problems (Weiss & Hechtman, 1986).

Second, children with attention deficits are at elevated risk for achievement difficulties, and many meet special education placement criteria as learning disabled (McGee & Share, 1988). Because children with ADHD in the classroom are typically off task, noisy, disruptive, and out-of-seat, and do not finish school work or homework, both parents and teachers complain of underachievement. These children's work can be highly inefficient and disorganized, and their performance often shows great fluctuations. Consequently, there may be a grave discrepancy between a child's estimated potential for learning and actual achievement in school. To make matters worse, there is suggestive evidence that children with ADHD may score an average of one-half to one full standard deviation below age-mates on standardized tests of intelligence. Even though there are competing explanations for this discrepancy (see Barkley, 1990), there is reason to worry that these children do experience a delay in the development of some cognitive strategies (Whalen, 1989). Because of academic difficulties, many of these children experience grade retentions and other school failures. These failures combined with their problem behaviors and tendency to alienate peers place them at great risk for negative feedback from parents, teachers, and the peer group. It is little wonder that they are also at risk for low self-esteem and depression as they mature. Even though this is a relatively new area of inquiry, the possibility of internalizing disorders must also be considered during the assessment process.

Third, many children with ADHD experience disturbed peer relations and are considered by others to be highly aversive playmates (Landau & Moore, 1991). As a consequence, they are frequently rejected by peers. Indeed, negative reputation can be established after only brief contact with unfamiliar children (Pelham & Bender, 1982). This rejected status is not surprising, as these children can be bossy, intrusive, disruptive, and easily frustrated while in the play group. They appear to have few, if any, friends. Peer rejection is a serious outcome for children with ADHD, as children who experience rejection early in life are known to be at high risk for many adult outcome difficulties, including job dismissals, bad conduct discharge from the military, police contact and incarcerations, and psychiatric hospitalizations (Parker & Asher, 1987).

Legal Requirements that Guide Assessment

It is important for school psychologists to understand relevant legal issues pertaining to the assessment of children with attention deficits. Evaluators must adhere to a careful and systematic identification plan to ensure that referred children suspected of having ADHD are not misidentified, overidentified, or underidentified. Schifani, Essex, and Wright (1992) even suggest that mistakes in assessment may lead to academic injury and, ultimately, charges of educational malpractice.

The process of assessment is complex and exacerbated by many variables. First, the characteristics of the disorder (i.e., inattention, impulsivity, and overactivity) are common to many children in the general population. However, it is only when these characteristics are excessive and/or developmentally inappropriate that a child should be identified as having a significant attention deficit. Second, children who do have an attention deficit may not present all symptoms representative of the disorder. Thus, there is extreme heterogeneity among children with ADHD. Third, the symptoms of ADHD often co-occur with a number of other disorders such as conduct disorder, and the symptoms may also be mimicked by associated problems such as abuse.

In 1991, the U.S. government issued a memorandum that clarified how children with ADHD qualify for special educational services as mandated by the Individuals with Disabilities Education Act (IDEA) and Section 504 of the 1973 Rehabilitation Act. Certainly, students who meet eligibility criteria for learning disabilities or serious emotional disturbances could receive services through those categorical placements. However, this memorandum made clear that children with ADHD may also qualify for special education support — under the Other Health Impaired category — as well as related services, solely on the basis of the attention deficit when it impairs educational performance (Aronofsky, 1992). The term attention deficit disorder does not appear in the IDEA, but this law does not attempt to provide an exhaustive list of chronic or acute health problems in the definition of "other health impairments." Thus, even though this category had long been available to serve children with health problems, it had largely been overlooked as a method of accessing special education services for children with attentional deficits (Latham & Latham, 1992).

The IDEA and Section 504 supply the foundation for identifying our responsibilities for proper school-based assessment of children with ADHD. However, school psychologists should be familiar with other laws regarding the education of these children. The Federal Civil Rights Act and the new Americans with Disabilities Act are examples of federal legislation that stress the requirement of schools to appropriately address the needs of children with disabilities. Also, awareness of the current litigation surrounding the issue of ADHD is important. Information about these laws and litigation is available through a variety of sources (Aronofsky, 1992; Latham & Latham, 1992; Martin, 1991). In addition, the Individuals with Disabilities Education Law Report can be obtained from LRP Publications, 747 Dresher Road, P.O. Box 980, Horsham, PA 19044-0980, (215) 784-0860.

The evaluation requirements under the IDEA and Section 504 for children with attention deficits are not unlike those for children with any suspected disability:

- A child must be evaluated before school personnel can begin programming.
- The parents must be involved in the evaluation process.
- The child must be evaluated in all areas related to the suspected disability.
- The evaluation team must include at least one specialist with knowledge in the area of the suspected disability.

In addition, evaluations must be kept current and are required at least every three years, or more often if (a) a parent or teacher request it, (b) if other conditions warrant it, or (c) if significant changes are to occur in the child's program. If a parent disagrees with the school's evaluation, the parent may obtain an independent evaluation which the school must use in educational programming decisions. Schools may even utilize identical evaluation processes and procedural safeguards for both the IDEA and Section 504 compliance.

The IDEA requires public schools to use a multidisciplinary team to identify and evaluate children having, or suspected of having, a difficulty. The purpose of the IDEA is to ensure that all children with disabilities have access to a free, appropriate public education that emphasizes special education and related services designed to meet their individual needs. Additionally, it ensures that the rights of children with disabilities and their families are protected. The purpose of Section 504 is to end discrimination against individuals with disabilities and to improve educational services for them. It requires that:

1. Students with disabilities be educated to the maximum extent possible with nondisabled peers.
2. Educational agencies identify unserved children with disabilities.
3. Evaluation procedures be improved in order to avoid the inappropriate education that results from misclassifying students.

The intervention implications of Section 504 are somewhat different than those of the IDEA, in that they do not require a need for special education as an eligibility condition. Thus, children who do not meet the criteria for services under the IDEA may be served under Section 504 if their attention deficit limits one or more major life activities, such as learning. In either case, careful attention to assessment issues is essential as a basis for providing appropriate services to these children.

Issues of Diversity

As school psychologists begin to design their assessment protocol for children with attentional deficits, it is imperative to maintain an understanding and appreciation of the diversity inherent in our society. Diversity extends beyond race and ethnicity, to differences in language, socioeconomic status, gender, age, religion, and ability. Schools are filled with all types of children, some of whom need support to be successful learners and, ultimately, contributing members of their community. The consensus is that the prevalence of ADHD is neither higher nor lower among different cultures (Barkley, 1990). It is clear, however, that social, cultural, and economic factors can play a significant role in the adjustment of children with ADHD and the impact they have on their families. Parents' level of education, family income, and family stability often dictate the resources available to deal with the medical, educational, and behavioral challenges these children present. Cultural and religious factors may also affect the perspective taken towards the child's problems. Thus, when assessing these children, consideration must also be given to these issues.

In 1992, the Office of Special Education Programs (OSEP) initiated an effort to identify critical issues that must be addressed to provide a free appropriate public education for children from culturally and linguistically diverse backgrounds. This initiative includes children with ADHD from diverse backgrounds. The final task force report identified "assessment as a critical issue" of concern, suggesting that certain groups are over- or under-represented in programs for children with disabilities and for gifted and talented students. This task force identified several strategies for change including:

- Utilize assessment and placement procedures that do not use a model designed to find and fix deficits.
- Ensure that all assessment procedures and tests used for sorting individuals have been validated on a population representative of the culture of the individual being assessed.
- Utilize authentic, reliable, and valid multilingual, multicultural techniques designed to promote student growth and development.
- Ensure that alternative assessment techniques are sensitive to culturally and linguistically diverse students.
- Utilize instructionally relevant assessment in schools that focuses primarily on process and outcomes of education.
- Provide educational personnel with the resources to become effective participants in authentic assessment processes that consider the cultural background of the students being evaluated (Federal Resource Center, 1993).

These suggestions are appropriate for any assessment protocol designed for children with attention deficits. As school psychologists, we must remain sensitive to differences among children and advocate the use of assessment procedures that do not misidentify, over-identify, or under-identify children with ADHD because of their background.

BEST PRACTICES

Assessment in a Problem-Solving Paradigm

As suggested by the recent position statement on students with attention disorders by the National Association of School Psychologists (National Association of School Psychologists, 1992), many school psychologists have approached the assessment of children with attention deficits as a diagnosis-driven undertaking, while investing significantly less attention to the development and monitoring of school-based interventions. Thus, some teachers may be well aware of the fact that enrolled in their classroom is a child with a diagnosable attention disorder. Unfortunately, they receive little collaborative efforts or support after the classification has been determined. However, the consultative model of Bergan and Kratochwill (1990) offers a useful problem-solving paradigm that can be translated into a flexible and dynamic assessment strategy to be directly linked to intervention planning and implementation. Thinking in terms of problem identification, problem analysis, plan implementation, and problem evaluation, school psychologists can collaborate with parents, school personnel, and community professionals to address the needs of children with attention deficits. In this way assessment is extended well beyond ADHD as a diagnosis and becomes, instead, an ongoing, problem-solving process.

The *problem identification* stage involves multiple objectives. For example, the school psychologist needs to determine precisely which behaviors evoke concern from significant others. Parent and teacher interviews, as well as omnibus rating scales completed by these informants, represent excellent strategies to accomplish this. By reflecting a normative perspective, rating scales also permit the school psychologist to determine the child's symptom severity or degree of deviance from age-mates regarding the behaviors of concern. Assessment during this phase continues until enough data are assembled to determine that a discrepancy exists between the child's current and desired levels of functioning (Bergan & Kratochwill, 1990). Direct observations in the natural setting can also prove useful for this purpose, especially if contrast observation data are collected on nonreferred same-gender classmates.

During the *problem analysis* stage, the school psychologist would identify the variables leading to the problem solution and develop an intervention plan to meet the stated objectives. During this phase, there are two major foci of the assessment process. The first is to establish the child's present abilities and resources to assist in meeting the objectives of the intervention (i.e., to determine if the concerns are due to a skill deficit or a performance deficit). In this case, individual psychoeducational testing may be warranted — both traditional norm-referenced and nontraditional curriculum-based measures. Second, variables external to the child, but within the environment and responsible for maintaining problem behaviors, would be assessed. For this purpose, further interviewing of teachers and parents about relevant events (e.g., the nature and timing of eliciting stimuli surrounding the presentation of inappropriate behavior), plus direct observations to precisely determine controlling variables, would be conducted. At this point, the specific intervention plan would be designed. In addition, tactics of implementation would be formulated, and the intervention evaluation would be planned (Bergan & Kratochwill, 1990).

During the *plan implementation* stage, the role of assessment is to ensure that the plan is being dispensed as formulated and to permit sensitivity to unintended consequences of the intervention. Thus, for example, child or consultee (parent, teacher) behavior would be monitored for the purpose of establishing treatment integrity (i.e., to determine that the intervention is being dispensed as planned). Additionally, if the child with attention deficits was to receive psychopharmacological treatment in school, a checklist or rating scale designed to assess treatment-emergent symptoms (i.e., medication side-effects) should be administered.

Finally, during the *problem evaluation* stage, assessment continues to determine the extent to which intervention objectives have been met. Thus, assessment data would compare the child's performance at this stage with the desired goals previously specified during the problem identification stage (Bergan & Kratochwill, 1990). As before, interviews, rating scales, and direct observations could all be used to assess treatment efficacy. If, however, the assembled data reveal that some goals have not been met, further assessment would be indicated for the purpose of returning to problem analysis.

The preceding discussion highlights the fact that a comprehensive and efficient assessment of children with attention deficits involves procedures serving multiple purposes. The same assessment method could be repeated several times as the reasons for conducting the assessment change. Thus, for example, direct observation of behavior may:

- Indicate potential areas of concern during the problem identification state.
- Reveal controlling variables in the environment to facilitate problem analysis.
- Serve as a measure of treatment efficacy during problem evaluation.

In addition, a comprehensive assessment of children with attention deficits must reflect a protocol comprised of several necessary components. First, it must engage *multiple methods* of assessment. Each method (interview, rating scale, or direct observation) can account for only a portion of the description of the child. Thus, a sufficient assessment uses numerous and diverse procedures. Second, assessment should depend on *multiple informants*. Parent(s), every teacher, the child, and even peers can each contribute unique information about the problem. Multiple sources are critical in the assessment of children with attention deficits because:

- Different informants may evoke different behaviors from the same child.
- Informants vary in terms of their respective expectations and demands placed on the child.
- Each informant is embedded in a unique environment (i.e., parents are primarily exposed to home-based problems, whereas peers are more familiar with problem behaviors in the free-play setting).

It is known, for example, that mothers of ADHD boys may experience more serious discipline problems at home than do fathers (Barkley, 1990).

Finally, children with attention deficits should be assessed in the context of *multiple settings*, as data are consistent in documenting that these children do not present the same problem in a trans-situational fashion. Teacher reports, for example, may vary considerably as a function of differences in classroom structure and curricular demands. Also, children with ADHD may be relatively unremarkable on the playground but quite distinctive in the classroom. And, the child's behavior during individual testing in the school psychologist's office may have no implications for classroom behavior. Obviously, specific setting differences need to be integrated in the details of problem identification, problem analysis, and ultimately, problem evaluation.

Specific Assessment Procedures

Given the view presented earlier, assessment is an ongoing process and progresses with various objectives in mind. Throughout this process, school psychologists need to consider the entire range of potential difficulties that could be experienced by the child with attention deficits. Thus, it is not sufficient to determine the extent to which the child exhibits inattentive, overactive, and impulsive behaviors (plus a specification of settings and situations in which these problems present): One must also focus inquiry on the potential for secondary characteristics typically found in samples of children with attention deficits. These include conduct disorder, academic difficulties, disturbed peer relations, and the internalizing problems of self-esteem deficits and depression. If the school psychologist concludes that the child does, indeed, have problems in any of these areas, the determination should be based upon a developmental perspective (i.e., the child was found to behave in age-inappropriate fashion). This means that the school psychologist must have a sound knowledge of normative or age-appropriate behavior and use assessment procedures that include components with adequate normative data. Ultimately, this developmental perspective also provides relevant and realistic goals for the intervention plan (i.e., the child will be expected to behave in age-appropriate ways).

Rating scales. Behavior rating scales are an important component in the assessment of children with ADHD. The reader is encouraged to consult Barkley (1990) for a summary of the psychometric properties of numerous scales as well as their advantages and disadvantages. Rating scales allow practitioners to determine the degree to which a child exhibits certain characteristics relative to same-age and same-gender students. In addition, they collapse information across situations and time, and provide insight into concerns experienced by those individuals who work and live with a child. This also permits a cost-effective method of data collection on infrequently occurring behaviors likely to be missed by more direct methods. However, the weaknesses of rating scales must be acknowledged. For example, results from these scales simply represent the opinions of others and do not capture the uniqueness of the child's style nor the strengths he or she presents. In addition, rating scales reflect the limitations of any retrospective report, such as distortions in memory, misunderstanding of scale items, and informant bias. These data may also be influenced by cognitive, social, emotional, or educational characteristics of the rater. Thus, the results of these indirect measures should be interpreted with caution: They do not portray the child's actual behaviors but, instead, the informant's impressions of that behavior.

Dykman, Raney, and Ackerman (1993) have identified 42 rating scales that have been used to describe or diagnose children with ADHD. Some of these instruments were developed to assess the primary symptoms associated with the disorder, while others were designed to evaluate situational variation in problem behavior. In addition to the many scales identified by Dykman et al. (1993), numerous other rating scales may be useful in assessing comorbid symptoms and disorders or targeting adjustment factors within the family. Instruments such as the IOWA-Conners Scale (Loney & Milich, 1982), the Revised Behavior Problem Checklist (Quay & Peterson, 1987), Social Skills Rating System (Gresham & Elliott, 1990), and the Children's Depression Inventory (Kovacs, 1980/81) may provide valuable information regarding potential secondary characteristics exhibited by children with ADHD.

Due to the extensive array of currently available rating scales, selecting an appropriate scale can be a confusing task. One must carefully evaluate the psychometric properties of a particular scale as well as consider the age of the child and the quality of the norms. In addition, the particular questions to be addressed by that stage of the assessment process must be taken into account. If, for example, ratings were to focus on problem identification, an omnibus scale such as the Child Behavior Checklist would seem appropriate. However, if one needed to assess the child's response to medication, the Conners (1969) Teacher Rating Scale, known to be drug sensitive, would be a better choice. School psychologists should never allow preference for a particular scale to drive the assessment process: The questions under investigation determine instrument selection.

During the first stage of assessment, problem identification, school psychologists should select and utilize rating scales as a strategy to delineate specific reported concerns about the child. Because rating scales are quite sensitive to setting effects, it is helpful to have as many individuals as possible having direct contact with the student complete these. They give the school psychologist a better understanding of who views which behaviors as problematic and how perceived differences in degree of deviance vary as a function of setting effects. In order to have confidence in the reliability of the data, teachers should have at least 6 weeks of familiarity with the student being rated (Edelbrock, 1983).

During problem analysis, a careful review of data collected from rating scales can be invaluable in developing intervention plans. Not only can these data reveal specific concerns as a function of informant (e.g., the mother reports significantly more oppositional and defiant behavior than her husband), but differences in symptom severity as a function of setting may indicate where interventions must be implemented. For example, a child with attention deficits may have difficulty following directions and completing assignments only with the math teacher. This determination would evoke an hypothesis (to be further assessed by other methods) that the problem behavior may be situational or setting-specific in nature.

For problem evaluation, rating scales are invaluable as an objective method of assessing the child's response to intervention. By readministering the same rating scales to those informants who previously provided data for problem identification, the school psychologist will be able to make a baseline versus response-to-treatment comparison. Indeed, these scales should be administered intermittently throughout the intervention to ensure their continued potency.

Cognitive and educational assessment. Because the attentional difficulties presented by children with ADHD can interfere with the educational process, assessment of academic functioning must be considered. Standardized tests of cognitive ability and achievement can be useful for problem identification. Also, many states require these norm-referenced tests to determine eligibility for special education services, including those for the learning disabilities frequently experienced by students with ADHD. Unfortunately, tests such as the *WISC-III*, *Stanford Binet—4th Edition*, *Kaufman Assessment Battery for Children*, or any norm-referenced achievement test can not be used to reliably identify students as ADHD. In addition, they have limited value for the development of a remedial plan. However, in combination with a teacher interview and record review, standardized test data will assist in determining that an achievement problem does exist.

If the child with ADHD does exhibit academic problems, criterion-referenced tests and curriculum-based measures show much promise in delineating the student's academic needs and strengths. Being the most sensitive to academic growth, these nontraditional methods of academic assessment should be used for problem analysis and are also appropriate for problem evaluation. A compilation of the academic portfolio (i.e., a collection of work samples over time) will also reflect changes in the student's performance and, therefore, is extremely useful in monitoring progress and evaluating the effects of intervention.

Interviewing. Interviewing procedures are essential in the assessment of children with attention deficits and can serve multiple objectives. Interviews with parents and teachers are an effective means of building rapport and, for problem identification, highlight specific areas of concern about home- and school-based problems. Although frequently overlooked, interviews also provide parents and teachers an opportunity to say what they like about the child. Second, for problem analysis, interviews can reveal controlling variables and the settings and situations in which the problems occur. Third, interviews permit the school psychologist to determine potential reinforcers that parents and teachers consider most salient to the child and to tap into the resources of parents and teachers functioning as consultees during plan implementation. Another often ignored value of interviews is in helping the school psychologist discover parents' and teachers' attitudes about, and acceptability of, a particular intervention (see Elliott, 1988), thereby having implications for treatment integrity. Thus, interviews not only offer specific information about the challenges presented by the child with attention deficits and have direct relevance for the design of an intervention, they also permit the school psychologist to gain better understanding of the consultees who may implement the intervention. It is important to note that those respected standardized interview schedules currently in use that are organized to reflect psychiatric diagnostic criteria, even those that facilitate differential diagnosis, have limited value for designing an intervention and are best reserved for research purposes.

Some features specific to parent interviews need to be considered. Clearly, parents are the best informants regarding the child's developmental and medical histories. For example, specific thought should be given to establishing the presence of tics in the child or history of tic disorders in biological relatives, as this fact can affect the suitability of psychostimulant treatment for the child. Second, because many children with attention deficits present oppositional and coercive behaviors at home, the parent interview should be designed to reveal potential problems in the parent–child relationship. Consistent with Barkley's (1990) suggestion, this should be done in terms of the eliciting activities or situations about which the parents experience the greatest difficulty. Thus, the school psychologist will learn not only which problem behaviors are presented by the child, but also where, and under what circumstances, they are presented, information crucial to the development of an intervention. In addition, differences between parents regarding their respective management strategies should be explored.

Because many children with ADHD can be extremely stressful to parents and may contribute significantly to marital discord (Fisher, 1990), it is important for the school psychologist to be sensitive to the impact that the child has on the entire family system. Parents should be asked questions pertaining to peer and sibling relationships which can be a source of great difficulty. Also, the child's general emotional state should be the focus of inquiry, and questions pertaining to self-esteem deficits and depression should be presented. Finally, the school psychologist should ask a series of questions to establish a prioritized list of parental concerns (i.e., which problems are most important to address first), the most salient reinforcers available to the parents, and the parents' motivation and ability to follow through on home-based recommendations. The reader is advised to consult Barkley (1989; 1990) for detailed guidelines on developing a parent interview.

Just as with parents, there are issues specific to the teacher interview that should be pursued. For example, to establish a functional analysis of behavior, the school psychologist should query teachers about inappropriate classroom behavior as a function of varying settings and structure. Given that many children with ADHD experience problems adjusting behavior as environmental expectations change (Landau & Milich, 1988), questions about transition time (e.g., going from recess to the classroom; lining up for lunch) should be included in the interview. Questions from the School Situations Questionnaire (Barkley, 1990) provide numerous other activities that could be the focus of this interview, and the teacher should be asked about the child's work habits and style of academic performance. Questions should target difficulties related to carelessness, disorganization, sloppy handwriting, and problems related to inefficiency. In addition, the teacher interview should pursue the child's ability to comply with commands at school and establish if problems in the peer group are present. If any of the above areas emerge as potential indicators of a difficulty, then further assessment is necessary to permit problem analysis. The interview should permit the school psychologist to assess resources available to the teacher to permit an effective school-based intervention, and special consideration should be made regarding the teacher's need for collaborative support from the school psychologist and other professionals working with the child.

Finally, some mention should be made of a direct interview with the child. Obviously, the purpose of this interview will depend on the age and maturity of the child, but it is a good practice for several reasons. First, this contact will facilitate rapport for subsequent sessions and will permit the school psychologist to observe the child directly. In this context, one should consider the child's language development, ability to comply with directions, and the degree of overactive/fidgety symptoms and inattention during the interview. However, it is important to remember that the presence or absence of particular behaviors during the interview may not be diagnostic of the child's actual problems outside the psychologist's office. And, the school psychologist must remain cautious when interpreting what the child actually says about problems at home or school. Children's self-reports are notoriously less reliable than reports from other informants, and children with ADHD have been found to deny about 50% of the problems attributed to them by their mothers (Landau, Milich, & Widiger, 1991).

Direct observation. Based upon informant concerns that emerge from the use of interviews and ratings scales, the school psychologist should then conduct systematic observations of the child with attention deficits, as these data will provide unique information. If the school psychologist observes the target child and all same-gender classmates engaged in the same activity, the resulting data can contribute to problem identification. For example, if the teacher complains about a boy who "never seems to get his math workbook problems completed; he daydreams constantly instead of doing his work," this boy's duration of on-task behavior can be contrasted with the average duration of all male classmates. These contrast data will not only establish if a problem does, in fact, exist but also suggest a realistic level of performance to serve as the intervention objective. Second, direct observations are necessary for problem analysis: They further clarify what the child is actually doing, and provide important information about the settings and situations in which problems occur. Thus, observations represent the best method of identifying controlling variables in the environment, a necessary component of the intervention design. Third, observation data can be used for plan implementation and provide information about treatment integrity. For example, the school psychologist may observe in the classroom to determine if the teacher is dispensing strategic feedback as prescribed. Finally, direct observations can establish the efficacy of an intervention (i.e., problem evaluation). Thus, direct observations can serve multiple assessment purposes and offer the most direct and ecologically valid behavioral data.

Unfortunately, no single observation system considered appropriate for all children with attention deficits exists. Instead, selection of particular code categories, specific recording methods to use (e.g., duration versus event recording), and the various settings for observation should depend on the informant concerns that emerged during problem identification. In any case, it is crucial to observe the child with ADHD in multiple settings and situations. For example, the school psychologist may seek to determine differences in classroom performance as a function of small- versus large-group activities, teacher-directed versus self-paced academic seatwork, highly structured versus informal classroom settings, and restricted academic versus freeplay activities. Because different situations account for much of the variance in observed child behavior, resulting data should always be considered in the context of a particular setting.

When selecting a particular observation system, the system's potential to capture relevant information about specific areas of concern serves as the single most important criterion. In most cases, the system should at least be sensitive to the occurrence of inattention, motor excess, and impulsive responding in the classroom. The interval recording system described by Abikoff, Gittelman-Klein, and Klein (1977) is one excellent example. In addition, if problem identification reveals difficulties with peer relations, observations should be conducted when the child is engaged in freeplay behavior (e.g., on the playground; see, for example, Landau, Milich, & Whitten, 1984). Even though the use of these systems requires some training prior to implementation, they can provide data for the design of interventions not readily available through any other method of assessment.

Laboratory methods of assessment. During the past two decades, much interest (and money) have been invested in laboratory and computer-driven methods to assess children with attention deficits. For example, Kagan's Matching Familiar Figures Test — a match-to-sample procedure — is a standard lab measure of impulsive responding, albeit with serious problems (see Milich & Kramer, 1984). In addition, numerous versions of the Continuous Performance Task (the most marketed one being Gordon's Diagnostic System) have been used to quantify vigilance or attention in the lab. Even though their putative objectivity and efficiency is appealing, several inherent limitations should be kept in mind. Obviously, school psychologists must consider the psychometric properties of these various procedures. Equally important, but significantly more daunting, is the question of ecological validity. Under the best of circumstances (i.e., adequate normative data and sufficient reliability and validity), knowing the child's performance on one or more of these lab techniques contributes little to an understanding of how the child functions in the classroom. In addition, these procedures are incapable of revealing controlling variables that could be targeted for intervention. Thus, even though these computer-driven devices may have heuristic appeal to some and are considered by others appropriate for problem identification, they have questionable utility for problem analysis and should not be used for an intervention evaluation.

Assessment of medication effects. Since most children with ADHD experience a trial of psychopharmacological therapy sometime during their childhood, the school psychologist should be familiar with the best practice in the assessment of medication effects. This is particularly important, as it is known that a given dose of psychostimulant medication does not exert the same therapeutic effect on all domains of functioning for a given child or across children. In addition, many prescribing physicians tend to rely on parent anecdotal reports to determine proper dosage, especially if systematically collected data are not available. Thus, dose effects must be considered as part of the assessment process for children with attention deficits. The reader is encouraged to consult Gadow, Nolan, Paolicelli, and Sprafkin (1991) for a description of a school-based model of medication evaluation involving rating scales and direct observation data.

Whichever assessment protocol is ultimately adopted, the school psychologist should supplement it with the use of a Parent Daily Report sent home at the end of each school day (see Pelham, 1993). This procedure has high ecological validity and is designed to directly reflect the concerns of parents and teachers. It provides for the specification of agreed-upon and operationalized targets of intervention (both academic and social) and presents the child's daily performance in these areas. For example, the number of workbook problems correctly completed or frequency of inappropriate rough play during recess could be evaluated among several targets. As recommended by Pelham (1993), one person in the school (usually the school psychologist) should be identified as coordinator of medication assessment, and would be responsible for establishing collaboration among parents, teachers, and physician regarding the specification of targets. With the use of a Parent Daily Report, the child's performance is monitored on a daily basis (rather than the more typical once-weekly use of ratings and observation), and the parents are given daily feedback regarding the child's response to medication.

Clearly, any intervention applied to the child with ADHD should be monitored for the purpose of problem evaluation. However, with psychopharmacological therapy, there exists an additional concern that must also be assessed; that is, the possibility of treatment-emergent symptoms or side effects. To this end, Pelham (1993) provides an example of the standard side effects rating scale appropriate for school use.

Guidelines

The following guidelines, which have been modified from Barkley (1990), are suggested for the school-based assessment of children with attention deficits. These guidelines should not be considered a rigid chronology for the assessment process but, instead, a flexible model for decision making that can be linked directly to the planning and evaluation of interventions.

1. Identify the major concerns of referral sources, and apply a developmental perspective to establish degree of deviance from age-mates. Rating scales and interviews are efficient and appropriate methods here.

2. Begin to cluster specific concerns into areas of developmental domains of functioning (e.g., motor, language, social, emotional, academic) and into settings or situations of occurrence (home, school, free play with peers, community).

3. Conduct direct observations in all settings in which problems reportedly occur. This is done to (a) verify informant concerns, (b) further establish degree of deviance and treatment goals by concurrently observing child and same-gender classmates, (c) determine relevant situation/setting effects that may account for differences in informant reports, and (d) isolate controlling variables in each setting that may be suitable targets for intervention.

4. Rank-order the apparent problems and developmental concerns into a hierarchy of troublesomeness/seriousness for this case. This will help establish which interventions should be applied first and which can come later.

5. Identify unique aspects of this case that may have implications for treatment planning. Some examples include:

- Make note of particular features in the classroom environment that could compromise a prescribed behavioral intervention.
- Develop an understanding of parent and teacher acceptance of potential interventions being considered.
- Assess parent and teacher ability to serve as consultees during the intervention process.
- Establish child characteristics that could relate directly to the selection of a particular intervention (e.g., social skills training designed to increase rates of interaction will not be suitable for an assaultive child).

These unique aspects can be identified through the use of interviews and direct observations.

6. In collaboration with parents and teachers, list all interventions that seem appropriate to each area of dysfunction or delay, and make determination based on previously established resources, treatment acceptability attitudes, and strengths noted in the child.

7. Design and apply specific interventions according to hierarchical list of concerns and the unique features of this case.

8. Assess treatment integrity using direct observations.

9. Conduct problem evaluation with rating scales, direct observations, and Parent Daily Report.

10. Conduct posttreatment follow-up using previously applied assessment methods.

A BEST PRACTICE MODEL

The Broward County Public Schools in Ft. Lauderdale, Florida, which is committed to meeting the needs of children with attention deficits in the regular classroom, has developed an assessment model based on the use of the Intervention Assistance Team (IAT). As such, the following does not reflect an assessment protocol for school psychologists per se; it represents a problem-solving approach applied by school personnel, including the school psychologist.

Each school designates a contact person to whom all requests for assistance are made. This school-based contact person reviews each request and then channels it to the school's multidisciplinary team (IAT). The school psychologist and the team then enters into problem identification/problem analysis phases by reviewing records, conducting interviews and observations, collecting rating scale data, and consulting with the child's teacher to develop a plan of action. This plan may include such strategies as further clarifying child characteristics or environmental factors that could be interfering with the child's progress, implementing and evaluating classroom interventions, or referring the child and/or family to an outside service agency. If this level of intervention does not prove sufficient to meet the child's needs, the case is further reviewed by the IAT.

When the IAT reconvenes, they evaluate the problem based upon the data collected and, in collaboration with the family, determine if the student meets the 504 classification as a qualified individual with disabilities. If the child is considered an appropriate candidate for 504 services, parents, teachers, and support personnel collaborate in planning accommodation strategies that meet the child's needs and develop a 504 Accommodation Plan. This plan specifically addresses the kind of modifications needed:

- Physical arrangements of the classroom.
- Nature of lesson presentation and work assignments.
- Test-taking methods.
- Ways to help the student get organized.
- Suggestions for managing the child's behavior (including medication needs).
- Special considerations. For example, does the bus driver need support in managing the child with ADHD? Does the child's teacher need more information about the disorder?

Thus, the team extends its consideration to all others with whom the child has contact.

Once the 504 Accommodation Plan has been developed, a school-based case manager, responsible for completing a Section 504 record form is assigned to the child. This accommodation record form indicates the specific areas of difficulty for the child, the accommodations to be made, the date to start the accommodations, the person responsible for implementing the accommodation, as well as a specification of the means of outcome evaluation. It is the case manager's job to monitor the plan and set timelines for implementing and evaluating the accommodations. Parents receive copies of the Accommodation Plan and the Section 504 record, along with a formal notice of the rights afforded to them by Section 504.

If the accommodations described on the Section 504 record form are ineffective, the case is resubmitted to the school-based assistance team for review. The team, along with the family, makes one of two decisions at this point. First, it is determined whether to redesign and modify the accommodations on the Section 504 record form. If this decision is made, the student continues services with monitoring by the case manager. The other options available to the team may include: psychoeducational evaluation, a dropout prevention program, alternative educational services, and remedial services.

Broward County has taken a clear position that most students with ADHD can be educated in the regular program with the help of appropriate interventions. Evaluation of these interventions is viewed as an essential component of the assessment process, regardless of whether the child is served in the regular program or receives support through special education.

The Broward County Public Schools have developed a range of materials that describe its assessment model. These include a handbook outlining procedures used to implement Section 504 of the Rehabilitation Act of 1973, a series of forms enabling schools to comply with the guidelines, and a videotape illustrating the process. For further information and/or copies of these materials contact Dr. Merrick Kalan, 600 S.E. 3rd Ave., 8th Floor, Ft. Lauderdale, FL 33301. Send $25.00 to cover the cost of the materials and make checks payable to School Board of Broward County.

SUMMARY

Assessing students who exhibit notable difficulty with sustaining attention, impulsivity, and overactivity represents a challenge for school psychologists. Many of these children present not only the primary characteristics associated with ADHD, they also have co-existing conditions such as conduct disorder, learning disabilities, and significant problems with peer relationships. Schools are required to provide a free, appropriate education to children with ADHD, which includes an evaluation if attention problems are interfering with the child's ability to be educated.

A problem-solving paradigm, based upon Bergan and Kratochwill's (1990) consultative model, is proposed to guide the evaluation process for students whose attentional problems are negatively impacting their school performance. The paradigm encompasses

1. Problem Identification: The school psychologist determines specific behaviors causing concern in the school setting.

2. Problem Analysis: Variables that permit attainment of a solution are identified. They may include intervention development and psychoeducational testing.

3. Plan Implementation: Accommodations are made and treatment integrity is monitored.

4. Problem Evaluation: The assessment process continues in order to determine the extent to which objectives have been met.

Specific school-based assessment strategies are discussed including rating scales, direct observation techniques, and interviewing techniques, as well as intellectual and achievement testing. In addition, a description of a model program in a local school system is described.

ANNOTATED BIBLIOGRAPHY

Barkley, R. A. (1990). *Attention-deficit hyperactivity disorder: A handbook for diagnosis and treatment*. New York: Guilford.

The most comprehensive and scholarly text pertaining to children with attention deficits. Although some of it seems more suitable for clinic-based practitioners, many chapters are extremely relevant for the school psychologist. These include an exhaustive review of rating scales and an excellent discussion of classroom-based modifications and interventions.

Welsh, R., Burcham, B., DeMoss, K., Martin, C., & Milich, R. (1992). *Attention-deficit hyperactivity disorder diagnosis and management: A training program for teachers*.

This is an excellent in-service training program that school psychologists can use to enhance the knowledge base of teachers regarding the assessment and treatment of children with ADHD. Developed by the collaborative efforts of the University of Kentucky's Departments of Psychiatry and Psychology, it is available from the Kentucky Department of Education, Nancy LaCount, Division of Special Learning Needs, 500 Mero Street, Frankfort, KY 40601.

CHADDER, published by Children with Attention Deficit Disorders (CH.A.D.D.), 1859 North Pine Island Road, Suite 185, Plantation, FL 33322, (305) 587-3700.

This newsletter, published by the active parent-support group for children with ADHD, can provide helpful information to parents and teachers regarding assessment, treatment, and legal/placement issues.

DuPaul, G. J., & Stoner, G. (1994). *Assessment and treatment of attention deficit hyperactivity disorder in the schools*. New York: Guilford.

This text provides a comprehensive review of ADHD in the context of a school setting. Issues of school-based identification and intervention are thoroughly discussed. In addition, the authors review topics such as how to involve families, as well as students, in the educational process.

AUTHOR NOTE

Sincere appreciation is extended to Richard Milich and Mark Swerdlik whose helpful comments and suggestions contributed significantly to this chapter.

FOOTNOTE

[1] The term ADHD will be used throughout this chapter to refer to children and youth with attention-deficit hyperactivity disorder or undifferentiated attention deficit disorder.

Best Practices in Assessment and Intervention with Children with Low Self-Esteem

E. Scott Huebner
University of South Carolina

OVERVIEW

School psychologists often are asked to consult with teachers who view children's problems as a manifestation or result of low self-esteem. In support of such concern, numerous psychological theories emphasize the importance of positive views of oneself and one's capabilities as a prerequisite to favorable psychological and educational adjustment. Indeed, research has demonstrated that children with high self-esteem are active, expressive individuals who tend to be successful in academic and interpersonal contexts. They display confidence and optimism about their abilities, social skills, and personal qualities. They initiate rather than passively listen in group discussions, are eager to express their opinions, and are not particularly sensitive to criticism. Overall, they experience a greater internal locus of control.

In contrast, children with low self-esteem tend to report feelings of isolation, anxiety, and self-consciousness. They are more sensitive to criticism and are thus less likely to assert their opinions or needs. They are more readily discouraged, giving up easily in the face of difficulties or avoiding challenges altogether. Finally, they experience greater difficulty in accepting others, leading to interpersonal conflicts. In summary, children with negative views of themselves will likely be at a considerable disadvantage compared to their counterparts with average or high self-esteem. (See J. A. Hattie, 1992, and Silvernail, 1987, for reviews.)

This chapter provides an overview of (a) selected self-concept measures, (b) special issues in the assessment of self-concept (e.g., use with special populations), (c) correlates of self-concept (e.g., demographics, family variables), and (d) intervention studies. These topics will be addressed within a general problem-solving framework; which has previously been applied to such areas as personality assessment (Knoff, 1990), consultation (Bergan & Kratochwill, 1990), and individual therapy (Goldfried & Davison, 1976).

BASIC CONSIDERATIONS

Definitional Issues

The past several decades have seen increasing interest in the theory and measurement of self-concept. Crain and Bracken (1993) report that more than 11,000 studies of self-concept have been published from 1974 to 1992 alone. Along with the increase in research, a proliferation of self-concept scales has emerged.

Before providing a brief historical overview of changes in self-concept theory and measurement, I should at this point define "self-concept." This is no easy task; numerous authors have provided a variety of definitions. Some authors distinguish between self-concept and self-esteem. For example, Rosenberg (1979) has defined self-concept as "the totality of the individual's thoughts and feelings having reference to himself as object" (p. 7). Self-concept is thus defined broadly to include an individual's total set of possible descriptions of herself or himself, not all of which may be evaluative in nature. The term "self-esteem" is restricted by some to the descriptions or beliefs to which a person attaches a positive or negative evaluation (e.g., Coopersmith, 1967). Self-concept thus describes individuals' perceptions of themselves, and self-esteem reflects their evaluations of their perceptions (Silvernail, 1987). Although these terms can be distinguished conceptually, research has not supported their differentiation (Shavelson, Hubner, & Stanton, 1976; Bracken & Howell, 1991). Rather, the research suggests that self-concept and self-esteem are "in fact a single construct or two very closely related constructs" (Bracken & Howell, 1991, p. 325). Thus, the terms will be used interchangeably throughout the chapter.

Changing Models of Self-Concept

Early self-concept research was based upon models that posited a unidimensional construct (e.g., Coopersmith, 1967). Self-concept was thought to be best conceptualized and assessed by combining an individual's self-evaluations across items tapping a diverse range of content domains (e.g., behavior, competence, affect, physical appearance, peer acceptance). The items were given equal weights and summed to derive a total score reflecting an individual's global self-concept. However, different instruments emphasized different domains during test construction, often yielding measures producing equivocal results.

Unidimensional models have been challenged by those who argue that such approaches mask important distinctions that individuals make in evaluating themselves in relation to various facets or domains in their lives (e.g., Harter, 1982; Wylie, 1974, 1979). Current research has provided strong support for the multidimensionality of self-concept (see Bracken, 1992; Harter, 1989; Marsh, 1988; Shavelson, Hubner, & Stanton, 1976). Such approaches yield profiles of self-evaluations across the particular domains included in the self-concept measures. For example, in a conceptual review of the self-concept literature, Bracken (1992) identified six specific domains that have been supported empirically in numerous research studies of children from age 8 to 18 approximately. These domains included family, social, competence, academic, affect, and physical. Evaluation of each of these domains, in addition to a global evaluation, enables a more differentiated assessment of children's self-concepts, which can produce more focused intervention plans. Obviously, interventions would differ for a child whose self-concept difficulties were limited to the family domain, compared to one whose difficulties involved primarily the academic and competence domains. The greater specificity of the multidimensional models has generated much support for their use in applied work.

BEST PRACTICES

Problem Identification

Problem identification requires the assessment of self-concept from a multidimensional framework. During the problem-identification stage of the problem-solving model, the school psychologist must determine in which domain(s) the child manifests negative self-perceptions. In the next section, six of the major self-concept measures are described, and issues related to their use are discussed.

Measures of Self-Esteem

Piers-Harris Children's Self-Concept Scale (The Way I Feel About Myself) (PHCS) (Piers, 1984). The PHCS is a widely used 80-item self-report questionnaire that has been researched extensively. It consists of simple declarative sentences (e.g., I like being the way I am; I have many friends) to which the child responds "yes" or "no." Reading difficulty is at approximately the third grade level; thus the scale is not recommended for students below the fourth grade level.

The PHCS was normed on 1183 children in grades 4–12 from one Pennsylvania school district. Internal consistency reliabilities for the total score range from .88 to .93. Test-retest correlations range from .42 (eight months) to .96 (three to four weeks). Concurrent validity estimates in the form of correlations with other self-concept measures range from .32 to .85. Although this scale was originally conceptualized as unidimensional, the manual provides six subscale scores: Behavior, Intellectual and School Status, Physical Appearance, Anxiety, Popularity, and Happiness/Satisfaction. However, because factor analytic studies have yielded inconsistent findings, Piers (1984) encourages caution in interpreting the subscales.

The Self-Esteem Inventory (SEI) (Coopersmith, 1984). The SEI School Form is a 58-item self-report scale designed "to measure evaluative attitudes toward the self in social, academic, family, and personal areas of experience" (Coopersmith, 1984, p. 1). There is an eight-item Lie Scale incorporated within the scale as well. The items are worded as brief statements (e.g., My parents and I have a lot of fun together; I'm pretty sure of myself) to which the student must respond with "like me" or "unlike me." Also available is a 25-item short form that correlates .86 with the long form.

The manual includes data from several large, but inadequately described normative samples. Users are strongly encouraged to develop local norms. Internal consistency reliabilities are reported as ranging from .87 to .92 for the total score for children in grades 4–8. Test-retest reliability for the SEI was originally reported by Coopersmith (1967) to be .88 (five-week interval) for a sample of 50 fifth graders and .70 (three-year interval) for a sample of 56 children. Fullerton (1972) reported a correlation coefficient of .64 (one-year interval) for a sample of 104 children in grades 5 and 6. Numerous studies support the concurrent validity of the SEI total score. Factor analytic studies have not provided consistent support for the hypothesized subscale scores, thus leading Harter (1990) to conclude that "the Coopersmith Inventory total score will provide a general estimate of self-esteem that may be fruitfully used as a first screening assessment, but will not provide a meaningful profile of domain-specific evaluations" (p. 297).

The Self-Perception Profile for Children. (SPPC) (Harter, 1985). The SPPC, which is available from the author, is a revision of the Perceived Competence Scale for Children (Harter, 1982). This 36-item scale, designed for students from ages 8 to 15, yields subscale scores for five competency or skill domains. Scholastic Competence, Social Acceptance, Athletic Competence, Physical Appearance, and Conduct/Behavior. Internal consistency estimates for the various subscales range from .73 to .86.

Concurrent validity has been demonstrated with a variety of self-concept scales. Factor analytic studies reported in the manual consistently have revealed a five-factor structure. Its most controversial feature is its unique item format. Children must respond by marking "really true for me" or "sort of true for me" to one of two alternative statements for each item (e.g., Some kids are happy with themselves as a person; Other kids are often not happy with themselves). Although designed to reduce social desirability responding, this response format is difficult for some children to understand, thus limiting its usefulness (Witt, Cavell, Heffer, Carey, & Martens, 1988). It should be noted that there are separate versions for younger children (The Scale of Perceived Competence and Social Acceptance for Young Children [Harter & Pike, 1984]) and adolescents (The Self-Perception Profile for Adolescents [Harter, 1988]).

Self-Description Questionnaire–1 (SDQ–1) (Marsh, 1988). The SDQ–1 is a 76-item self-report scale designed for use with students ages 6 to 11. Based upon Shavelson, Hubner, and Stanton's (1976) multidimensional self-concept model, it consists of eight subscales: Physical Abilities, Physical Appearance, Peer Relationship, Parent Relationship, Reading, Math, General-School, General Self. The SDQ–1 displays good internal consistency, with coefficient alphas all in the .80s and .90s for its subscales. Numerous studies are reported in the manual demonstrating convergent and discriminant validity. Extensive factor analytic research has supported its hypothesized factor structure, providing support for the usefulness of the various subscale scores. There are separate versions for adolescents (SDQ–II [Marsh, 1990]) and college students (SDQ–III [Marsh, 1991]). To date, the major limitation of the SDQs is that the normative data for all three versions have been obtained exclusively from students in Australia.

Self-Esteem Index (Brown & Alexander, 1991). The Self-Esteem Index is an 80-item self-report instrument based on a multidimensional model incorporating four domains: familial acceptance, academic competence, peer popularity, and personal security. An estimate of global self-esteem is derived by summing the responses to all 80 items. The test was standardized in 1988 and 1989 on 2455 students age 8–10 and 11–18 from 19 states. The demographic characteristics of the sample compare favorably to comparative U.S. population statistics with respect to gender, race, domicile, geographic region, ethnicity, and parental educational attainment. In short, the standardization data were excellent.

In contrast to the standardization, less effort was expended on reliability and validity research. Internal consistency estimates were acceptable, most falling in the .80s and .90s throughout the age range. However, test-retest data were not reported. Concurrent validity studies demonstrated encouraging correlations with similar measures (Piers-Harris, Coopersmith); nevertheless, all of the studies included less than 30 subjects from restricted age ranges. Finally, although preliminary factor analytic data supported the multidimensionality of the subscales, the correlations between the subscales and criterion measures were unacceptable in several instances (e.g., .04 between Academic Competence and Coopersmith's School-Academic scale; .29 between Peer Popularity and the Piers-Harris Popularity scale). Although this instrument is highly promising, additional validation work is needed before it can be used confidently in diagnostic decision making with individuals.

Multidimensional Self Concept Scale (MSCS) (Bracken, 1992). The MSCS is the most recent addition to the plethora of self-concept scales potentially available to the school psychologist. The 150-item scale is appropriate for students between 9 and 19 years of age. The scale requires students to rate items by degree of agreement using a modified Likert format with no neutral option (i.e., strongly agree, agree, disagree, strongly disagree). The MSCS was designed to assess individual's self-perceptions across six contexts: Social, Competence, Affect, Academic, Family, and Physical. An equal number of items is included in each scale.

The standardization data were obtained from 2501 students (ages 9–19) from 17 sites located in all major regions of the United States. The MSCS sample closely matches U.S. population demographic characteristics. Total scale internal consistency reliabilities range from .97 to .99 for each age level and the total sample. Subscale reliabilities range from .87 to .97. Test-retest reliabilities are reported as .90 for the Total scale score and .73–.81 for the subscales. Several studies have supported the convergent and discriminant validity of the scales. A large-scale joint factor analysis of the MSCS with the Coopersmith Self-Esteem Inventory, Piers-Harris Self-Concept Scale, Self-Esteem Index, and the Tennessee Self-Concept Scale has provided support for the six dimensions (Bracken, Bunch, Keith, & Keith, 1992). Although research with the MSCS is just beginning, the instrument appears especially promising as an individual clinical assessment tool, particularly given its outstanding norms and careful development.

Issues in the Assessment of Self-Concept

The use of any of the above measures must be tempered by several considerations. The first issue involves developmental differences in the structure and content of the self-domains. Regarding the structure, some researchers (Harter, 1989; Marsh, 1990) have provided tentative empirical support for the notion that an increasing number of domains can be differentiated by children as they mature. For example, Harter's self-perception scale for adolescents

BEST COPY AVAILABLE

includes three domains (close friendships, romantic relationships, and job competence) that are not included in the preadolescent version. The addition of these domains is thought to reflect not only developmental advances but also changes in the concerns of adolescents.

Another developmental limitation is demonstrated in the fact that "young children are incapable of making judgments about their global self-worth" (Harter, 1990, p. 303). That is, it is not until middle childhood (approximately age 8 and above) that children can make conscious, reliable verbalizations about global self-esteem. Taken together, these developmental issues suggest limitations in the use of any *one* instrument with children of all ages. A given instrument may be particularly appropriate to the concerns of one age range, but not appropriate to the concerns of another age group. Thus, sensitive assessment of the self-concept across different age groups may require different assessment strategies and instruments.

The second issue involves the use of self-report measures of self-concept with special populations, such as children with handicapping conditions or children from different cultural settings. Because self-concept measures have been developed mostly for use with "normal" school children, their use may present unique problems with special populations. Some children may not possess the skills to respond to the self-report scales as intended. Among children with mild mental handicaps and learning disabilities, Harter and her associates (Renick & Harter, 1989; Silon & Harter, 1985) have found differences in the factor structures of her instruments compared to nonhandicapped children. For example, she obtained a two-factor solution to the SPPC with a group of mildly mentally retarded children, ages 9 to 12. This finding suggests that mildly mentally handicapped children differentiate among fewer domains than their nonhandicapped agemates. With students with learning disabilities, additional factors have been defined. Not only is scholastic competence differentiated from athletic competence (as well as the other SPPC domains), but general intellectual ability is differentiated from the specific skills involved in particular school subjects (e.g., reading). As a result of such findings, Harter revised the SPPC for use with learning disabled (LD) students to assess academic and general cognitive perceptions independently. Without separate subscales, a user might inadvertently derive the wrong conclusions regarding the cognitive self-perceptions of an LD child.

Although little cross-cultural research has been done, particularly with regard to the specific domains of self-concept (J. A. Hattie, 1992), similar cautions likely apply. That is, users of popular self-concept scales must be especially cautious with handicapped and culturally different children.

The final caveat involves the use of self-report scales of any kind with children and adolescents. Self-report scales have long been considered suspect by some because of problems such as social desirability, unclear observable referents, and poor agreement with ratings by others and with observed behavior (see LaGreca, 1990; Witt, Heffer, & Pfeiffer, 1990). Nevertheless, the difficulties surrounding the assessment of children's covert, internal states via other assessment techniques (e.g., teacher and parent report, direct observation) have prompted the development of more psychometrically sophisticated self-report methods such as those described above. Thus, at present, the school psychologist would be wise to conduct a multimethod, multiperson assessment. Multiple methods and raters are desirable to overcome the limitations of any one procedure or individual's perspective. Thus, comprehensive, multimodal approaches, including such procedures as parent and teacher interviews and/or ratings and behavioral observations, are likely to be essential in developing the most accurate picture of the child's self-concept.

School psychologists must be cautious, however, in extrapolating from self-evaluations to behavior. As J. A. Hattie (1992) has noted, self-perceptions may guide behavior, but in many instances it does not. Also, not all individuals monitor or control their self-presentations consistently (Snyder, 1987). Different children may manifest low self-esteem with disparate behaviors (e.g., acting-out behaviors, withdrawn behaviors). Since many factors mediate the relationship between self-concept and behavior, it should be apparent that a strong, one-to-one correspondence between a child's self-concept ratings and particular behavior(s) across situations is unlikely.

Not surprisingly, few formal, standardized behavioral measures of self-concept have been developed (Chiu, 1987; Hughes, 1984). Those that have been developed have received little research attention. Also, to my knowledge, no multidomain behavioral measures have been developed. Consequently, the school psychologist must rely upon behavioral indicators specific to the individual case. Possible behavioral examples from Chiu's (1987) research include: hesitates to speak up in class, adapts poorly to new situations or new tasks, becomes upset by failures (e.g., by pouting, whining, withdrawing), gets along poorly with peers, gives in to others easily, tends to dominate or bully other children.

Finally, self-concept data need to be integrated with all other assessment and background data. For example, Bracken (1992, Appendix D) in a useful table describes the overlap between his MSCS domains and more than 100 commonly used psychoeducational instruments, such as behavior rating scales, adaptive behavior inventories, omnibus personality and adjustment inventories (e.g., MMPI) and projectives (e.g., sentence completion, apperception tests).

PROBLEM ANALYSIS

Problem analysis encompasses a description of the child's areas of low self-concept and an understanding of the variables that might cause, support, or maintain the low self-concept. This process is accomplished through an analysis of intrapersonal and environmental forces that may be influential for a given individual. One may develop working hypotheses concerning possible antecedent variables by examining the existing research base on self-concept and its correlates. The following discussion will focus on research related to demographic, family process, school, and cognitive process variables.

The relationship between demographic variables and self-concept has been investigated in several studies. There is little evidence for consistent, systematic differences in global or domain-specific self-concepts as a function of age, gender, race, or socioeconomic status, as measured by occupational status or income (Bracken, 1992; Wylie, 1979). Thus, there is insufficient support for the widely held notions that self-concept decreases when children enter adolescence or that disadvantaged children show lower levels of self-concept than middle-class children.

Although social status variables have little, if any direct relationship with self-concept, J. A. Hattie (1992) suggests that their effects may be indirect, operating through family process variables. J. A. Hattie's review shows considerable support garnered for Coopersmith's (1967) conclusions about the family antecedents of self-concept: acceptance of children by their parents, clearly defined and enforced limits, and respect and latitude for children's behavior within defined limits. Self-concept is thus related to parental evaluations, interests, and expectations, all of which provide stimulation for the child's developing self-concept.

Self-concept also has been investigated in relationship to school variables. For the most part, this literature has revealed few meaningful, reliable findings. However, there are suggestions that teacher expectations as well as students' perceptions of their teachers' expectations relate to self-esteem. For example, some evidence suggests that students who feel liked and respected by their teachers have high self-concepts, while those who believe they are disliked by their teachers have lower self-concepts. Also, teachers described as displaying democratic leadership techniques coupled with a relatively low degree of negative evaluations have been associated with students with higher self-concepts (for reviews of the influences of school variables, see J. A. Hattie, 1992; Silvernail, 1987). These findings are not surprising in light of the findings regarding family influences.

Finally, various intrapersonal variables have been found to relate to self-concept. Most important, research suggests that high self-concept is correlated significantly with cognitive processes, such as attributions for success to ability and to effort (Marsh, Cairns, Relich, Barnes, & Debus, 1984). Students with higher academic self-concepts tend to demonstrate a more internal locus of control, attributing outcomes to their own actions rather than to external events or chance. In contrast, students with low self-concepts tend to blame others or external conditions or chance. Low self-concept students have also been found to self-reinforce less frequently than do high self-concept students (Ames & Felkner, 1979).

INTERVENTION

Although many standardized intervention programs have been designed to improve self-concept, few have demonstrated validity. Self-concept intervention studies have been categorized by J. Hattie (1992) as falling into three general categories: cognitive-behaviorally oriented programs, affectively oriented programs, and programs neither cognitively nor affectively oriented.

Cognitive-behaviorally oriented programs assume that changing an individual's thought patterns (e.g., negative self-statements) will change the feelings and behavior that characterize and maintain low self-concepts. For example, rational-emotive therapy (RET), in which children are taught specific strategies to dispute unrealistic, irrational cognitions related to low self-concepts, has been applied to children and adolescents (DiGuiseppe & Bernard, 1990).

Attribution retraining approaches also assume that an individual's cognitions influence the intervention process. Specifically, attribution styles theory maintains that a low self-concept is mediated by global, stable internal attributions for failures. Change efforts therefore attempt to modify attributions based upon failure to reflect attributions based upon lack of effort, coupled with positive statements about ability, whereas attributions based on success are modified by encouraging self-reinforcement based on effort and ability (Craven, Marsh, & Debus, 1991).

Cognitive-behavioral approaches also include personal development programs (e.g., social skills training, vocational training, values clarification) communications skills courses, and transactional analysis approaches. See Pope, McHale, and Craighead (1988) for an example of a *multidimensional* cognitive-behavioral approach.

Affectively oriented programs rely upon efforts to increase an individual's awareness of her or his feelings, which presumably impede the development of a positive self-concept. Such methods also focus heavily on the interpersonal relationships between clients and the therapist/change agent. J. Hattie (1992) described approaches based upon Adlerian, client-centered, and Gestalt models in this category, including such structured programs as the

Development of Understanding of Self and Others (DUSO) (Dinkmeyer, 1970) and the Human Development Program (HDP) (Human Development Training Institute, 1970).

Programs neither cognitively nor affectively oriented involve programs in which the intervention is not directed specifically at improving the self-concept. These include academic programs and physical fitness programs. Academic programs include those in which specific academic skills are taught. Such programs are based upon the assumption that improved academic competence will result in improved self-concepts (Scheirer & Kraut, 1979).

Programs with a focus on physical fitness and awareness (e.g., camp programs) have been developed to attempt to increase self-concepts. One of the most popular is the Outward Bound Program, in which outdoor activities provide the context for increased mastery and improved self-perceptions (Marsh & Richards, 1988).

Following a comprehensive review of the literature, J. Hattie (1992) conducted a meta-analysis to evaluate the overall effectiveness of the self-concept modification techniques. Using studies involving both children and adults, she obtained 485 effect sizes from 89 studies suitable for inclusion in the analysis. The average effect size for the interventions was .37, and the average effect for the control group was .12. Based upon the assumption of a normal distribution, the data suggested that "65% of the people who undertook a program to enhance self-concept experienced change, whereas 55% of people involved in the control groups experienced change. This difference indicates that 10% of those who had some intervention had enhanced conceptions of self compared with those in the control groups" (J. Hattie, 1992, p. 227).

J. Hattie also compared the differential effectiveness of the three intervention approaches. The results revealed that the cognitive-behaviorally oriented approaches were the most effective, while the affectively oriented approaches were the least effective. The efficacy estimates of programs that were neither cognitively nor affectively oriented overall fell in between the other two categories; however, there was considerable variation among the approaches. For example, on the one hand, the intense outdoor programs, implemented in extra non-school residential settings (e.g., Outward Bound) had the highest average effect sizes. On the other hand, academic programs that attempted to enhance self-concepts by increasing academic achievement were typically ineffective.

Additional conclusions from the meta-analysis revealed that the self-concept interventions for children were most effective when the interventions used (a) therapists rather than teachers, (b) lower socioeconomic groups, (c) and domain-specific measures of self-concept rather than global measures. Overall, J. Hattie (1992) concluded that "it is possible to enhance self-concept using some form of intervention, although this change was not as great as many researchers would claim" (p. 236).

One shortcoming of many of the intervention studies conducted to date is that global self-concepts rather than specific facets have been targeted for change. Likewise, such studies have employed poorly defined global measuring instruments, rather than selecting multidimensional instruments with demonstrated construct validity that include the dimensions specifically pertinent to the intervention. As a result it is not surprising that the measured effects have been modest and/or ambiguous, because such measures may have masked improvement in specific domains of self-concept. Future studies that compare the effects of treatments on targeted specific domains with effects on nontargeted domains may further clarify the differential effectiveness of various interventions.

The implications for school psychologists are clear. They must assess multiple domains of self-concept to determine which *specific* domains to target in their intervention efforts. Subsequently, intervention efforts must be tailored to match the unique profile of self-perceptions of the particular student under consideration.

A useful example of a successful cognitive-behaviorally oriented self-concept intervention study is provided by Craven et al. (1991). This study will be explored in detail because it incorporated many of the aforementioned methodological improvements as well as illustrating several validated, specific strategies for enhancing particular facets of self-concept. The primary purpose of this intervention study was to enhance reading and mathematics self-concepts. They used a multidimensional self-concept instrument (i.e., the SDQ–1) to examine the effects of the intervention. Two forms of interventions, performance feedback and attributional feedback, were employed together to develop a more powerful intervention. Similar interventions based upon the two types of feedback were administered to late elementary age students, one by teachers and one by researchers over an eight-week period. The researcher-administered interventions were conducted in individual and small group settings, while the teacher-administered interventions were conducted in regular classrooms. Statements that focused on positive ability (Shunk, 1985) were coupled with statements that focused on performance feedback in order to encourage students to generate appropriate self-reinforcers. Such feedback, which has been termed internally focused performance feedback, was used to train students to transform low self-concept judgments to high self-concept judgments. Using Brophy's (1981) guidelines for praise, the internally focused feedback was contingent only upon appropriate gains in performance. Examples of internally focused feedback were "look at all the skills you have in mathematics. You can do lots of things well in mathematics. You must feel good about your abilities in mathematics."

Attributional feedback was also used to enhance self-concept. Attributional feedback involved attributing success on graded mathematics and reading tasks to ability or effort; and attributing failure to lack of effort, coupled with ability statements. Feedback was made contingent upon success or failure on tasks consistent with the ability level of the students. Examples of such feedback statements were "No, that's not right. You have the ability to do well and will do well when you try harder."

The results of this brief intervention demonstrated that the researcher-administered interventions were successful in enhancing academic areas of self-concept. Furthermore, the treatment effects were specific to the targeted areas (i.e., reading and math self-concepts), with no effects for nontargeted areas (e.g., physical, appearance, family self-concepts), with one exception (peer self-concept). In contrast, the interventions administered by teachers in the context of ongoing, every day classroom activities, did not produce significant changes in self-concept. The reasons for the differences between the success of the researcher- and teacher-administered interventions were unclear, but possibly reflected differences in the frequency of feedback that the teachers and the researchers were able to administer. Specifically, perhaps as a consequence of implementing the program with individuals or small groups outside the regular classroom, the researchers were able to administer almost twice as many verbal reinforcers as the teachers were over the course of the treatment.

Whatever the case, this study provides an example of a brief, relatively simple intervention that could be applied efficiently and effectively by school psychologists working with individuals or small groups of children. This study also underscores the benefits of highly focused self-concept intervention efforts. Furthermore, the study demonstrates the usefulness of careful and systematic assessment efforts. By specifying *a priori* predictions about which facets of self-concept should be affected by the interventions, as well as which facets should *not* be affected, the researchers established greater confidence in the specific links between the intervention and its outcomes. Finally, the study demonstrated the advantage of including measures of the processes (i.e., frequency of feedback statements) that were expected to be responsible for the self-concept changes. The inclusion of such measures enabled generation of a plausible, data-based hypothesis regarding the differential effectiveness of the treatment as a function of the particular intervention agent.

Research also has highlighted the importance of considering a student's particular frame of reference for his or her global and specific self-concepts (see Harter, 1985; Marsh, 1988). Researchers have long recognized that self-concepts are constructed with respect to one or more reference groups that serve as a basis of comparison. Consideration of this finding helps clarify seemingly paradoxical findings in the literature — for example, the lack of mean differences in the self-concepts of disadvantaged minority children and nondisadvantaged children. Such knowledge also points to an important caveat in designing interventions for children. Intervention agents must keep in mind possible changes in self-concept that may follow from changes in a student's reference group. For example, a student who is highly competent in academics in comparison to his regular class peers may suffer a decrease in academic self-concept when placed in a program for gifted students. Although the student's academic competence might actually increase during the program, his academic self-concept might decrease as a result of comparisons with his new, more gifted peers (J. Hattie, 1992). Similarly, a student who is performing well in comparison to his peers in a special education program may lower particular facets of academic self-concept following mainstreaming attempts.

The implication for school psychologists is that they should not simply administer a self-concept scale and then formulate "educated guesses" about a child's relevant reference groups. To the contrary, school psychologists should *directly* explore children's bases for comparisons. For example, Harter (1985) provides examples of age-appropriate, open-ended questions that can be used to ask students about relevant social comparison groups. Using such techniques, school psychologists will be in a better position to make predictions about changes that might be expected in a given child's self-concept as a result of potential intervention efforts.

EVALUATION

In the evaluation phase, the school psychologist must address the problem-solving process in general and the associated intervention specifically. The evaluation of a self-concept change program will likely involve repeated, direct assessment of a child's self-perceptions (e.g., changes on a self-concept scale, teacher behavior ratings) as well as any related change expectations (e.g., increased academic achievement, increased peer acceptance). As underscored in the previous sections, the school psychologist must select instruments and techniques that tap the specific areas of interest from a multimethod, multiperson perspective. In this manner, assessment is performed within a construct validation approach, thus assuring greater confidence in the assessment findings. For further information regarding general formative and summative program evaluation techniques, the reader is referred elsewhere (e.g., Maher & Bennett, 1984).

With regard to the intervention evaluation stage, one additional concern bears mentioning. The evaluator must be careful to distinguish between the validity of a self-concept measure and the accuracy of an individual's self-judgments (Harter, 1990). Consider the following example: Objective indicators of school performance (e.g., grades, teacher ratings) are moderately, but significantly correlated with students' perceived academic competence. Nevertheless, students are often referred who do not demonstrate the expected relationship between their actual competence and their perceived competence. Some children perceive themselves as "stupid" even though they are performing at the top of their class. Similarly, students may perceive themselves as unattractive despite obvious evidence to the contrary. Rather than simply interpreting the child's perceptions as inaccurate, it will likely be more fruitful to investigate the reasons for the lack of association between the child's perceptions and the more "objective" conditions. For example, in the former example, perhaps overly high parental expectations have been internalized by the child so that s/he perceives herself in an unduly negative light. In such a case, the school psychologist may need to target intervention efforts toward changing the parents' behavior and expectations as well as the child's (Bracken, 1992).

SUMMARY

This chapter has summarized the literature on self-concept and formulated a best practices approach to enhancing children's self-concepts from a problem-solving paradigm. Self-concept was defined broadly to include an individual's descriptions of her or himself, including evaluative descriptions. In contrast to early unidimensional theories of self-concept, the multidimensional perspective has received the most empirical support to date. Six frequently used multidimensional self-report measures of self-concept were reviewed, including the Piers-Harris, Coopersmith's SEI, Harter's SPPC, Marsh's SDQs, Brown and Alexander's Self-Esteem Index, and Bracken's MSCS. Given the outstanding national standardization and preliminary evidence of psychometric properties, Bracken's MSCS is an especially promising new addition to self-concept assessment.

Differences in the structure of self-concept have been reported for special populations, such as the handicapped. The integration of self-report instruments with other assessment data was proposed as essential to a construct validation approach and thus consistent with a best practices approach.

Self-concept has not been consistently related to age, gender, race, or socioeconomic status, but rather to a variety of family process variables, school environment variables, and intrapersonal cognitive variables.

Based upon a multidimensional perspective, interventions must be tailored to a student's unique profile of self-perceptions. The intervention for a student who displays negative family self-perceptions will need a qualitatively different treatment approach and different treatment context from that for a student who displays primarily negative academic self-perceptions. Likewise, a student who displays a circumscribed self-concept problem (e.g., negative self-concept in one domain) will perhaps require a less intensive intervention than a student who displays a more pervasive negative self-concept. In general, cognitive-behavioral interventions have proven more successful than affectively oriented interventions. The most successful self-concept programs have involved strategies aimed at enhancing self-concept (e.g., attributions retraining) along with direct academic instruction.

ANNOTATED BIBLIOGRAPHY

Canfield, J., & Wells, H. C. (1976). *100 Ways to enhance self-concept in the classroom: A handbook for teachers and parents.* Englewood Cliffs, NJ: Prentice-Hall.
This classic curriculum guide fof teachers and parents includes 100 activities that can easily be implemented in regular and special education classrooms of all grade levels.

Craven, R. G., Marsh, H. W., & Debus, R. L. (1991). Effects of internally focused feedback and attributional feedback on enhancement of self-concept. *Journal of Educational Psychology, 83,* 17–27.
This well-written article describes a brief group intervention that successfully improved elementary school children's academic self-concepts. The authors describe thoroughly the intervention, which could be implemented by school psychologists.

Harter, S. (1990). Issues in the assessment of the self-concept of children and adolescents. In A. M. LaGreca (Ed.), *Through the eyes of the child* (pp. 292–325). Needham Heights, MA: Allyn & Bacon.

This chapter provides a well-written scholarly discussion of issues in the assessment of the self-concepts of children and adolescents from a developmental perspective. Based upon much of this leading researcher's own work, this chapter provides thoughtful discussions of such complex topics as self-concept theories, developmental considerations, assessment with special populations (e.g., handicapped students), psychometric concerns, and children's awareness of self-processes.

Hattie, J. A. (1992). *Self-concept.* Hillsdale, NJ: Erlbaum.
This book provides a comprehensive, scholarly overview of self-concept research, including the author's own significant contributions. Included are chapters on theory, history, measurement, correlates, interventions, and dimensionality.

Pope, A. W., McHale, S. M., & Craighead, W. E. (1988). *Self-esteem enhancement with children and adolescents.* Needham Heights, MA: Allyn & Bacon.
This text describes a cognitive-behavioral intervention for self-esteem enhancement of children and adolescents. An overview of the theoretical and research support for the treatment approach is included, as is practical information, such as specific techniques for the identification of target children and recommendations for handling "unexpected difficulties" during intervention.

Best Practices in the Use of Standardized Assessments

Brian J. Stone
Wichita State University

OVERVIEW

Standardized tests alone do not provide complete and sufficient information for designing, implementing, and monitoring individual education programs. However, standardized tests can provide objective information that is unobtainable through other means. In particular, standardized tests quantify information through reference group comparisons. When funding is targeted for a specific percentage of the population, it is possible with standardized tests to identify the correct proportion. In addition, the scores (or estimates) can be used to generate ideas about problems and competencies that are *internal* to the child. Standardized tests can be used with other forms of assessment, such as ecological assessment (which provides information about problems external to the child). Indeed, different approaches can provide complementary information and are compatible, rather than mutually exclusive.

Every child possesses unique characteristics. Assessment of these characteristics allows us to reliably determine a child's inter- and intraindividual strengths and weaknesses. When tempered with information regarding a child's background, standardized test information can help provide an understanding of the child's current functioning and educational needs.

Regrettably, use of standardized tests is often dictated by state and district interpretation of federal policy. This has led to an overreliance on such tests for qualification scores. Further, more is expected of tests than tests can reasonably be expected to provide. Simply put, tests **sometimes** help to clarify the reasons for a child's learning problem; sometimes they do not. When used properly, tests are merely a means to an end, not the end itself. Because tests have been overused or misused in the past is no reason to discard them totally. Standardized tests are capable of providing relevant information in many circumstances (Reschly & Grimes, 1990).

There has been discussion in school psychology about a need for less emphasis on standardized assessment (e.g., Batsche, 1992) with a shift to curriculum-based assessment (which incidentally, can also be standardized). Fagan and Wise (1993) have argued for a continuation of the existing assessment framework, with the addition of other roles. Indeed, public law compliance mandates that the school psychologist's role include standardized testing. Rather than shift completely our role, chances are we will merely add to it (Fagan & Wise, 1993). Thus, informed use of standardized tests will continue to play a major part for the school psychologist.

The IQ test remains the most frequently administered standardized test in school psychology. However, over the past 10 years school psychologists have tended to use fewer IQ tests and more tests of achievement and adaptive behavior and behavioral checklists (Hutton, Dubes, & Muir, 1992). This trend will continue, as demonstrated in the lowered use of IQ tests in reevaluation situations (Reschly & Grimes, 1990).

Standardized testing information should not be overinterpreted. In order to avoid this trap it is important to be aware of psychometric characteristics of tests. Scores can sometimes reflect more of the attributes of a test than of a child. The first part of this chapter covers the psychometric attributes of test interpretation; the second part introduces the fourfold goal of test interpretation in clinical judgment: (a) Reliable inter- and intraindividual comparisons; (b) generation and cross-validation of hypotheses; (c) need determination; and (d) appropriate intervention decisions.

BASIC CONSIDERATIONS

Standardized Tests

Standardized (or norm-referenced) tests must be administered and scored according to uniform procedures in order for children to be compared with their representative reference group. Standardized tests include tests of ability, achievement, personality, and adaptive behavior. Assessment is a more general term than test, and typically refers to a broad range or battery of tests or procedures, covering more than one domain.

805

Standards

Standardized tests should meet certain criteria of test development, administration, and interpretation (Anastasi, 1988). As school psychologists trained in the scientist-practitioner model, we should make sure tests meet standards of reliability and validity before blindly placing faith in them to provide relevant information. The school psychologist is responsible to know the standards of empirical reliability and validity, as well as ethical guidelines for test use and interpretation — see *Standards for Educational and Psychological Testing* (AERA, 1985), *Ethical Principles of Psychologists* (American Psychological Association, 1992), and *NASP Principles for Professional Ethics*, Appendix I (NASP, 1984). This is particularly true for serving as an expert witness or participating in due process hearings. One has to be able to defend what one has done, both in the areas of psychometrics and clinical judgment.

Measurement Error

All tests have some error, as tests are merely samples of behavior used to estimate a theoretical true score. The accuracy of the estimate is a function of the reliability of the test and is operationalized by the standard error of measurement. The standard error of measurement is used to create confidence intervals. All obtained scores should be bracketed by confidence intervals in order to acknowledge the degree of error in the test. In this way, we not only admit that no score is exact, but we also quantify our degree of error.

Some tests bracket the estimated true score with asymmetrical confidence intervals (e.g., Wechsler Intelligence Scale for Children–Third Edition [WISC III; Wechsler, 1991], and the Differential Ability Scales [DAS; Elliott, 1990]), while others simply bracket the obtained score with symmetric intervals. The former technique is more sophisticated than the latter because it takes into account regression to the mean. The assumption is made that a person with an extreme score is likely to have a true score somewhat closer (regressed) to the mean. Therefore, the most accurate confidence limits are asymmetrical about the obtained score rather than being the same number of points above and below (symmetrically distant from) the obtained score.

Group Tests

Standardized group achievement testing can provide an objective reference point of how a child is doing outside the day-to-day curriculum of the classroom. Group achievement tests can be misused when there is no specified a priori plan for their use. If a district wants to see how it compares nationally, it would be more cost-effective to test a random sample from the district, rather than test all students. If there is a planned use for each individual's score, then all children should be tested. It is important to keep in mind, however, that if group and individual results seem discrepant, more confidence can be placed in the individual results (Hood & Johnson, 1991).

Sometimes a district uses group achievement testing results to evaluate teachers rather than the students. This is an inappropriate use of tests. Interestingly, quality teaching spreads the distribution (top students make great gains; poor students make very modest gains), which results in a larger standard deviation, but only a slight increase in the mean. If a district wishes to increase its mean, it should concentrate resources on top students to increase high outliers, which will pull the mean up. If the district desires to decrease variability, resources should be concentrated on poor students, which moves them up slightly (but does not do much to the mean).

Generalizability

A major assumption of standardized test data is that the results are generalizable. In other words, subjects' performance on the IQ or achievement test reflects their problem-solving level and style outside the testing situation (Sattler, 1988). The power of test scores in predicting relevant criteria such as school or work success is well established. Indeed, IQ tests are one of the few instruments that have predictive ability that extends years into the future. While IQ tests are less reliable and predictive for very young children, it should be noted that IQ scores are fairly stable for handicapped infants and toddlers (Kamphaus, 1993).

A child's behavior during the individual testing session is far less generalizable than the actual scores, however (Glutting, Oakland, & McDermott, 1989). This makes sense in that the classroom setting is much different from a one-on-one session with an examiner attempting to elicit the child's optimal performance.

User Friendliness versus Psychometric Sophistication

Interestingly, tests show a trade-off between user friendliness and psychometric sophistication. For example, the Kaufman Assessment Battery for Children (K-ABC; Kaufman & Kaufman, 1983) at the subtest level is user-friendly but psychometrically poor. The item sets within subtests allow a ceiling to be reached with only one failure if that is the last item within the set for a given age. While this is a very user-friendly technique for both the examiner and the child (allowing quick administration and limited frustration, respectively), it is poor measurement. Accurate measurement requires the child to obtain at least a few right *and* a few wrong items in order to estimate the child's ability level on any subtest. A child who gets all items right may have had "barely enough" ability to get them right, or far more ability than is needed. Conversely, a child who misses all the items may have had almost enough ability or not nearly enough ability to get one right. The same is basically true for only one right or one wrong — we simply do not have enough information to get an accurate measure of the child's ability.

This point obviously has relevance for floors and ceilings. Indeed, tests may have limited floors and ceilings at different age and ability levels. For example, Pattern Analysis on the Stanford-Binet IV (SB IV; Thorndike, Hagen, & Sattler, 1986) has an excellent floor and ceiling for young children and children at average ability levels (most children will obtain some correct and some incorrect responses). However, for gifted teens the ceiling is poor, as high-ability older children tend to "top out," receiving correct credit for all items. The obtained score is then a low estimate and can artificially lower the overall composite score.

Except for Pattern Analysis the SB IV seems to show the opposite problem in regard to high-ability teens: a high degree of psychometric sophistication (accurate measurement) at the expense of limited user friendliness (very lengthy testing session). For gifted teens the test can take well over 2 hours, yielding a very accurate score at the expense of examiner and examinee fatigue. The bottom line is that school psychologists should be aware of the trade-off between user friendliness and psychometric sophistication.

More Trade-offs

Assuming we have accurate measurement, what is the construct that is being accurately measured, and how do we intend to use it? For example, the Mental Processing Composite (MPC) of the K-ABC is obviously not highly *g*-loaded. Therefore, gifted children will tend to score closer to the mean on the K-ABC, and retarded children will tend to score higher than they would on the Wechsler Scales. The MPC will not be as predictive as a Wechsler Full Scale IQ (FSIQ). Knowing this, I still chose to use the K-ABC with Native American children of the Ute nation because verbal tests seemed to affect rapport and trigger defensiveness in some of these children. The Wechsler scales may have provided more useful information in a predictive sense, but at the expense of rapport. Therefore, clinical judgment and working with these children day to day mandated the use of the psychometrically poorer test!

Constructs

Some would argue that since the SB IV includes memory subtests in the overall composite, it is a poor measure of reasoning for the gifted child. Gifted children typically score lower (closer to the mean) on memory tests than on general mental ability tests, just as low-ability children score higher on memory tests (again, closer to the mean). This regression to the mean occurs because memory tests are lower on *g*, the general mental ability factor. In other words, people high on *g* regress to the mean on tests that are less *g*-loaded. Similarly, people low on *g* score slightly higher on tests that are low on *g*-loading. This phenomenon could lower a gifted child's score on the SB IV (or raise a mentally retarded child's score). Indeed, this phenomenon helps us to aticipate and explain why certain composites (e.g., processing speed) are closer to the mean than highly *g*-loaded composites (e.g., Verbal IQ) for extreme scorers such as gifted and retarded children.

It is a delicate business to balance between adequate psychometric measurement and user friendliness. However, the best tests manage to balance the need for psychometric sophistication with the need for user friendliness while making it clear to the user exactly what is being measured.

Outdated Tests

A frequently encountered ethical consideration in testing is use of an older test after a revision has been published. Outdated tests are not appropriate for placement decisions. This is because the child is compared with a noncurrent norm group. This practice results in inflated scores. School psychologists are sometimes guilty of saying a new test (e.g., WISC III) gives "lower scores." This is false. The new test yields correct scores. The older version of the test gives *inflated* scores. This is a very important point and school psychologists should be aware of it.

Interestingly, gifted children will seem to have even more of a "drop" on a new revision of a test. This is because regression to the mean is also at work. In other words, when an obtained score is extreme, there is a high likelihood that the true score is slightly closer to the mean.

Bias

Bias occurs when a test unfairly favors one group over another (Jensen, 1980). For example, the standardization version of the DAS (Elliott, 1990) had a picture of a cactus and the subject was asked to name it. Not surprisingly, children from the Southwest had greater familiarity with cacti and did much better on this item than children from the Northeast and North Central regions. The difference in item difficulty scores was not due to differences in ability level, but merely to differences in exposure to cacti. Thus, the item was regionally biased and was dropped from the final version.

Bias can also be operationally tested in a fairness-of-prediction model. A test would be biased if it had different predictive accuracy for one group than for another. Most IQ tests by this definition are not biased. For example, an IQ of 70 predicts difficulty at school no matter what the race or sex of the subject.

807

Similarly, a IQ of 130 predicts school success for a member of any group. Under this model, bias does not exist when two groups with unequal means on the predictor also have unequal means on the criterion (Stone, 1992).

IQ tests tend to remove or reduce the achievement content in problem solving. IQ tests actually avoid, or entail only in reduced measure, some of the perceived bias in achievement tests (i.e., mean differences in achievement test scores that result when one group has been exposed to less or allegedly poorer schooling).

Most modern IQ tests have succeeded in vastly reducing culture bias. For example, matrices-type tasks ("this shape goes to that shape as this other shape goes to . . .") are not specifically a part of any culture. The same goes for newer measures of intelligence, such as reaction time in simple information-processing tasks (Jensen, 1993). Even tests on which a great deal of verbal and cultural knowledge is required on nonverbal tasks (e.g., the performance subtests of the Wechsler scales) have not been shown to be empirically biased. Vocabulary tasks can be argued as being cultural, but among native speakers of the particular language from which the vocabulary is drawn, they are also probably the best single measure of intellectual functioning. This is because they require the integration of many high-level cognitive tasks; one must learn words through exposure, deduce meaning through context, and recall and express coherently their meaning. Highly *g*-loaded tasks appear to be important for successfully functioning in a complex technological society.

It is important to remember that low ability is just one hypothesis for explaining why a child has scored low on a test of ability. There are many other hypotheses (and combinations of hypotheses) to explain a low score (e.g., lack of environmental stimulation, limited exposure to educational materials and settings, distractibility, anxiety, major emotional trauma). However, most explanations for a low score would also tend to predict poor performance on a relevant criterion. There are exceptions, however, particularly when the contributing factors are more situational than chronic.

One area of potential bias that is often misunderstood is the standardization sample. Obviously, the sample should be selected so as to reflect the population. Some educators are concerned when the sample does not include persons with specific mildly handicapping conditions, or some other low-base-rate group. The inclusion of low-frequency groups does not change scores (a child who would obtain a score of 100, would also obtain a 100 if the entire sample were redone to include, for example, a 3% sample of Conduct Disordered children or Moravian immigrants). The intent is to compare scores with those of representative sample of the population. The inclusion of any low-incidence group in the sample will simply not change the normative scores to any great degree.

Summary

Before interpreting a test it is important to keep in mind certain things about both the test and the subject. Regarding the test one should be aware of measurement error, the floor or ceiling of the test, regression to the mean, and the relevance and validity of the test for the specific use employed. Regarding the child, factors to consider include the child's background, environment, language use, and social, medical, and educational history, as well as the past and current family situation.

BEST PRACTICES

Test Selection

Tests should be selected on the basis of specific referral question to be answered. The attributes of the test for the pertinent age and ability level should be known by the examiner. For example, a child 6 years, 1 month of age suspected of low ability would be better measured by the DAS (Elliott, 1990) or Wechsler Preschool and Primary Scales of Intelligence–Revised (WPPSI–R; Wechsler, 1989) than by the WISC III (Wechsler, 1991). The child would receive more correct responses on the first two in comparison with the latter, on which too few correct responses might be made to accurately gauge ability level. That is, better measurement for this child would come from the first two tests because of the attributes of both the child and the tests considered together.

Furthermore, one might have to look into the problem of including to the composites subtest raw scores of zero. While it is true that too many raw scores of zero give a poor measurement, to discard those subtests could falsely inflate the overall score. Each test handles this situation differently; information should be provided in the manual. While school psychologists are legally and ethically held responsible to follow manual recommendations, keep in mind that these recommendations are made by human beings and therefore sometimes come more from desperation than inspiration.

The child aged 6 years, 1 month would be in the very first norms table on the WISC III, which is the least accurate. Norms tables at 4-month intervals (such as on the WISC III) change a great deal from 6 years 3 months 30 days to 6 years 4 months 0 days. The DAS solves this by using 3-month-interval norms tables up to age 8 (beyond which less drastic raw score increases occur), after which 6-month-interval tables are used. The SB IV has 4-month intervals to age 6, then 6-month intervals to age 11, 1-year intervals through age 17, and a final 6-year norms table through age 23. Ideally, the most accurate norms

806

would be computerized versions that could conceivably have a different norms table for every day.

Explaining Constructs

It is a leap of faith to say that a test that requires a child to put cartoons in order measures "social planning." The test merely requires a child to put cartoons in order. The construct "social planning" is what we infer (however inappropriately) to be an underlying process. Sometimes our labels for constructs serve to confuse or overintellectualize the task. It is best to literally and succinctly describe what an assigned task is — for example, "On the Developmental Test of Visual–Motor Integration (VMI; Beery, 1989), *a test of copying increasingly more difficult shapes*, John scored in the range of . . ." This should be done prior to, or instead of, assigning a construct name to the task in the report (try to avoid jargon, e.g., "integrative visuo-spatial motor skills"). Our constructs quickly become confusing to parents and other professionals, hindering rather than facilitating communication.

Empirical versus Clinical Interpretation

Just as the various questions discussed above involved the psychometric and clinical attributes of assessment, test interpretation also makes use of this interactive dichotomy. An empirical approach is purely psychometric, while a clinical approach is more subjective and intuitive. Ideally, best practices would require a blend of the two. However, a wary eye must always be kept upon the psychometric aspects of a test to avoid being fooled into thinking that a test attribute is a child attribute. In the absence of sufficient knowledge of psychometrics it is easy to fall victim to overinterpretation and too much nonscientific thinking. However, in the absence of clinical knowledge it is easy to fall victim to identifying people with mere scores. When psychometric particularities are kept firmly in mind, clinical judgment makes a good companion.

Intelligence Testing with the WISC–R (Kaufman, 1979) set the standard for the empirical top-down approach to test interpretation. The most reliable score is the full scale composite score (because it has the most items). Therefore it is the score you can put the most trust in. The other composites and factors are somewhat less reliable. Less reliable still are the individual subtests, and finally, the individual items. The *Introductory and Technical Handbook for the DAS* (Elliott, 1990) goes a step further psychometrically, and demonstrates how reliability is a function of the ability level of a child. For example, the DAS subtest Early Number Concepts (ages 2:6 through 7:11) is reliable for all children ages 3 through 6. However, it is not reliable for low ability two-year olds, as they will not obtain enough correct responses to accurately measure their ability. Similarly, it is not reliable for high ability seven-year olds as they tend not to receive any incorrect items, therefore their ability is not accurately measured.

On the clinical side, the shared-abilities approach is a legitimate although admittedly "armchair" method of deriving meaning from a group of tests. It is assumed that subtests are measuring various abilities and that the child's pattern of subtest strengths and weaknesses reveals his or her underlying abilities and deficits. There is less empirical research in this area but it makes sense. However, one should not turn their back on psychometric knowledge when employing shared ability procedures.

Ideally, one would start psychometrically, but also be able to employ the shared-abilities method to generate hypotheses about the child. In addition, it is sometimes useful to "test limits" to further investigate hypotheses. For example, if time limitations seem to be an impediment, time limits can be avoided. However, this would not be according to standardized procedure and could not be scored as such. Incidentally, some tests (such as Pattern Construction on the DAS) are normed with and without bonus points for speed so that one can score it either way.

The psychometric and shared-abilities approaches can be combined. For example on the DAS, the subtest Copying (similar to the VMI: copying increasingly more difficult shapes) can be contrasted with Recall of Designs (copying increasingly difficult shapes from memory). We can assume that a child who does well on Copying but poorly on Recall of Designs has the requisite visual–motor skills but falls down in the area of visual memory. This hypothesis can be further explored and cross-validated on other tests of visual memory. This processing deficit in visual memory could explain why a child of average or above average ability shows far below average achievement. It is still only a hypothesis, however, no matter how much support we have from other tests. Our best guess would be that this processing deficit apparently is responsible for the lower than expected achievement. Furthermore, there is no magical way to teach a child with this (or any) particular pattern of strengths and weaknesses. Research has consistently shown the only way to improve a child's reading is by spending more time on reading (Kavale & Forness, 1987). Typically we look for ways to compensate (note-taking strategies, taping lectures, etc.) rather than to remediate. A child with this deficit might qualify as learning-disabled; and sometimes a label can help parents and teachers be more accepting, patient, and understanding of a child's uniqueness.

Some newer tests combine the psychometric quantification with the clinical processing style approach. For example, the California Verbal Learning Test for Children (CVLT-C; Delis & Kramer, 1993) quantifies simple verbal memory across trials, while also producing standardized information regarding memory strategy and learning curve. The CVLT-C gives scores that explain whether the child was remembering mainly the first or last things heard (primacy vs. recency), and to what extent the child uses semantic category grouping as a memory strategy. The CVLT-C offers promise for the future in terms of information that standardized tests can provide.

Significance versus Frequency of the Difference

An important psychometric consideration in comparing scores across tests is significance versus frequency of the difference. Significance of the difference between scores is the probability that the theoretical underlying true scores are equal. This is useful in seeing if a discrepancy between ability and achievement scores is "real" (meaning unlikely to have occurred by chance). In other words significance of the difference is a computation of how often the obtained difference in scores could occur from underlying true scores that are the same. The bottom line is that it merely tells us whether our underlying true score on one measure is probably different from our underlying true score on another measure. It is not the most useful clinical measure.

A more practical measure is frequency of the difference, which tells us exactly what percentage of the population walks around with this difference. Quite often we will find a difference to be statistically significant (say, $p < .01$), yet perhaps 20% of the population have such a difference (the underlying scores may be different but the magnitude of that difference is fairly common). Frequency of the difference gives us important real-world information.

Problem-Solving Model

Within the problem-solving model, standardized tests help us to (a) make reliable inter- and intraindividual comparisons; (b) generate and cross-validate hypotheses; (c) participate in needs determination; and (d) take appropriate action (e.g., intervention and placement decisions).

With a representative norm sample and accurate measurement of a reliable construct, both inter- and intraindividual comparisons are valid. It is useful to compare individuals with the reference group (nomothetic comparison), which provides information on relative strengths and weaknesses within the child. This information may help diagnose a certain condition, which can create a link to a data base (e.g., mental retardation, developmental learning disability). It will also provide information as to how extreme a condition is, as all our diagnoses in education exist on a continuum (there are no blood tests for the presence or absence of learning disability, behavior disorder, etc.).

Intraindividual (or ipsative) comparison refers to looking at the pattern of a child's scores for relative strengths and weaknesses. This can become complicated because people may have different reasons for having similar scores.

Many neuropsychologists use the "levels of inference" model. This model has four levels, and is very similar to Kaufman's approach (Kaufman, 1979). First is the general level, at which overall functioning (from IQ or other total composites) is compared with the reference group. Second, lesser composites and individual subtests are examined for patterns within the individual. Third, specific pathognomonic signs are noted (e.g., perseveration, echolalia, "constructional dyspraxia"). Finally left versus right distinctions within the individual are examined (grip strength, finger-tapping speed, etc.). This model builds in both nomothetic and ipsative approaches. The two approaches are complementary, not mutually exclusive.

We should not overinterpret from a single measure, particularly if that measure has questionable reliability and validity. For example, we might ask, "Does evidence for low self-esteem exist across diverse measures such as the Draw-A-Person, sentence completion tasks, social interaction, and so on, or do we just see a very small and lightly drawn Draw-A-Person without indications of low self-esteem across other measures and settings? The more settings and tests by which the hypothesis is supported, the more confidence we can place in it. On the other hand, too much testing can be redundant (there is usually no need to give a child two or three IQ tests).

Standardized tests do not specifically determine a child's educational needs unless the testing is linked to the curriculum. However, certainly knowing a child's age and grade level and what the child can and cannot do is relevant to needs determination. The information provided by tests is often summarized by the school psychologist in a team meeting. Intervention decisions are team decisions; therefore the school psychologist must use the relevant data provided by the tests and testing situation and express it without jargon to the other professionals.

We must have some faith (as well as some empirical knowledge) about the interventions prescribed. Prognosis is difficult when reduced to the individual level, and is more difficult the farther into the future prediction is to be made. Yet at some level we should be aware that the information we have gathered is fairly predictive of future functioning. Knowledge of predictive validity helps us to plan goals and objectives for the child. This information can also allow us to help the parent(s) to accept the child's exceptionality and its consequences.

SUMMARY

Standardized testing does not answer all the questions that arise in individual educational program planning, and sometimes it merely raises more questions (Is it indeed the child's weakness in visual/verbal memory that is causing the learning problem in reading?). Testing is useful for generating hypotheses that can describe the severity of a problem. Standardized testing does not address all information that is relevant for intervention decisions, such as what the child finds rewarding, whether the child has object permanence, and so forth.

Once a problem is clearly defined, standardized assessment can help to determine the nature of the problem (e.g., Is the child mentally retarded or is there a specific language delay?). This is useful information for designing and implementing interventions. However, in some instances IQ may be irrelevant (e.g., behavioral problems when ability to do the school work is not in question). Jensen (1980) has pointed out that it is far more relevant for a teacher to know how well a child has learned what has been taught than to know the child's IQ. Sometimes, though, standardized tests are useful for ruling out certain causal hypotheses such as severe cognitive deficits.

No single approach or test can supply more than a fraction of the information and insight necessary for investigating a child's learning problems. All forms of assessment are merely samples of behavior and therefore have limitations. Standardized tests can be used with other forms of assessment. Different approaches may provide complementary information. Indeed, it is best practice not to rely solely on any single approach, but to be prepared to combine all approaches to investigate the referral question most effectively and to develop information useful for interventions.

Best Practices in Personality Assessment

Howard M. Knoff
University of South Florida

OVERVIEW

The assessment of child and adolescent personality remains an important activity for the school psychologist, given the mandate of the Individuals with Disabilities Education Act (IDEA; Public Laws 94-142 and 99-457 and subsequent reauthorizations) to identify and provide services to severely emotionally disturbed (SED) students. Beyond IDEA, however, the personality assessment process helps us to better understand the significant number of social-emotional and behavioral problems that non-special education students manifest in today's schools and communities. Clearly, through personality assessment school psychologists can provide parents and educators with insight and direction into such problems as truancy, drug abuse, dropping out, teenage pregnancy, suicide, and the emotional impact of divorce, poverty, rejection, and academic failure. But, most important, school psychologists can provide these individuals with recommendations and action plans that decrease or resolve current child and adolescent problems and help prevent them in the future. This is the bottom line of personality assessment. Personality assessment is a process of collecting valid data to explain the causes for or contingencies relevant to a child's social-emotional, behavioral, or affective difficulties. This assessment is useless in isolation; it must be linked with viable, acceptable, and socially valid interventions that are successfully implemented with ongoing attention to treatment integrity and evaluation (Knoff, 1986).

Within a context of comprehensive school psychological service delivery, it is essential that school psychologists understand normal and abnormal personality development and apply this information to empirical models that explain children's social-emotional, behavioral, and affective development. In addition, school psychologists must identify what they want to accomplish from the personality assessment process, as well as what their school districts and multidisciplinary teams want from this process. Then, they must determine whether these two sets of goals converge. While the ultimate personality assessment goal is to develop and implement effective intervention programs for referred students, the following are also goals of the school psycnologist: to determine who "owns" a specific referred problem (e.g., the referred child, a referring teacher or parent, a dysfunctional system, or a combination thereof); to validate hypotheses explaining how a referred child's behaviors are being caused, encouraged, reinforced, or supported; to create a sound baseline of data so that intervention can be evaluated from an appropriate context and so that an accurate presenting history can be documented; and to identify the referred child's behavioral assets and the home's and school's resources so that they may be integrated into an intervention program.

Relative to the school district, the primary goal of personality assessment often is to determine a student's eligibility for special education services. This is a national tragedy, because it reinforces the serious misconception that a special education placement is, in and of itself, an intervention. Special education is a setting — ideally, the optimal setting in which to deliver an intervention program needed by a student. And if a special education placement is made in the absence of a functional personality assessment that clearly identifies the program in need, then the placement is, in essence, unethical.

School psychologists must discourage districts from requesting personality assessments primarily as a means to qualify students for a placement in a class for the severely emotionally disturbed. The following are more appropriate district-related uses of personality assessment: to identify and analyze recurring patterns of student behavior or affect so that effective preventive programs can be developed; to understand the severity and demands of students' social-emotional problems so that optimal staffing patterns can be organized; to investigate the relationship between unrealistic academic expectations and inappropriate student behavior so that curricular restructuring as appropriate can occur; and to address student problems that do not require formal referrals or special education placements through teacher consultation, staff development, and prereferral interventions. Ultimately, the best criterion for an SED special education placement is the student's resistance to intervention. Because a "best practice" personality assessment process determines needed intervention programs, placement decisions then can be related more to the success of these interventions than to an assessment process linked to supposedly measurable eligibility criteria.

Under ideal circumstances, school psychologists' professional goals for personality assessment will closely match those of their school districts. However, school psychologists often assess students from a perspective that integrates both psychology and education, while their school colleagues often focus only on an educational perspective. While this may create some tension within the school, the psychology-by-education context is the most effective through which to understand and respond to most referrals for personality assessment. Yet, parenthetically, this difference in perspective explains why school psychologists' assessment conclusions and program and placement recommendations for SED-referred students often differ from their colleagues on the multidisciplinary team: school psychologists are independently and interdependently analyzing referred students' psychological and educational status and outcomes, while others are assessing only the academic impact of these students' referred behaviors or interactions.

The need to analyze referred students from a psychology-by-education perspective is a "best practice" behavior for school psychologists. Children's behavior and affect are the interdependent products of the many institutions, settings, people, and contingencies with which they interact. Personality assessment must reflect these interactions through multitrait, multisetting, and multimethod analyses that necessarily involve data collection from home, school, and community sources (Gresham, 1983). School psychologists should never yield to an educational perspective that is not in the best interests of a student's educational and *psychological* needs and future. School psychologists must look at the child's entire ecology; the school setting is but one part of that ecology (Knoff, 1983).

Given the discussion above, it seems critical that school psychologists work from an empirical model that explains children's social-emotional, behavioral, and affective development from a psychology-by-education and ecological perspective. While this model must be sensitive to situation-specific behavior (Kenrick & Funder, 1988), it should nonetheless guide the school psychologist's thinking so that personality assessment becomes an empirically based problem-solving process that links directly to intervention and that integrates referred problems into a realistic and wholistic context. Significantly, a number of empirically derived models have been developed to synthesize the research literature and to explain certain specific student outcomes (Centra & Potter, 1980; McKee & Witt, 1990; Rosenfield, 1987). These models have been synthesized into a single, summary model in which student outcomes have been operationalized as (a) academic skill outcomes, (b) cognitive/metacognitive skill outcomes, (c) social skill outcomes, and (d) adaptive behavior skill outcomes. While all four outcome areas can relate to personality assessment, b and c are the two that most directly relate.

As can be seen in Figure 1, the four outcome areas are directly and indirectly impacted (via the arrows shown) by eight different conditions or domains that exist in most students' worlds: family, neighborhood, and community conditions; school and school district conditions; within school and classroom conditions; teacher characteristics or conditions; teacher performance and teacher effectiveness conditions; curricular characteristics and conditions; student characteristics and conditions; and student academic behavior conditions. The point here is that it is usually very easy to identify the specific behaviors, emotions, or affects that are of concern with a specific referred student. What is not always easy to determine is *why* the behaviors are occurring. Using this model, hypotheses explaining why a student's behaviors are occurring can be generated and, once confirmed, they can be directly linked to specific interventions. The personality assessment process, then, focuses on the confirmation or rejection of hypotheses generated using this empirically derived model (Knoff & Batsche, 1991a).

Briefly, the six areas of the empirical model, as described previously (Knoff & Batsche, 1991b, pp. 177–180), are as follows:

1. *Family, neighborhood, and community conditions.* These involve characteristics or conditions of a referred student's family, neighborhood, and community as they relate ultimately to effective discipline and behavior management approaches and student social skills, self-esteem, and self-management outcomes. They emphasize the importance of a positive and proactive home environment and its impact on a student's school readiness, social-emotional development, and success.

2. *Within-classroom/school/district conditions.* These involve favorable and unfavorable characteristics and conditions within a referred student's classroom and school building, such as the physical plant, the pupil–teacher ratio, the presence of mental health resources (e.g., school psychologists and guidance programs), professional development opportunities for staff, the administrative and instructional organization of the building, and other conditions that explain teacher effectiveness. This area also extends to characteristics and conditions within the school dis-

STUDENT-SPECIFIC CHARACTERISTICS

FIGURE 1. Summary of ecological characteristics and conditions that impact student learning outcomes.

trict that impact classroom management and instruction and successful student achievement.

3. *Teacher characteristics/performance/effectiveness conditions.* These involve characteristics and conditions that teachers bring to the classroom that ultimately translate into the effective management and instructional skills and behaviors that support student learning and development (e.g., background characteristics, professional training). Also involved are those empirically identified skills, activities, and conditions of teachers that make their instruction effective and impactful (e.g., their ability to adapt instruction, their use of social skills curricula and behavior management techniques).

4. *Curricular characteristics and conditions.* These involve characteristics and/or conditions of the curricula being used and include content as well as the processes that are used to ensure student learning and mastery. Curricula here include the self-esteem, social skills, and other behavior management curricula that lead to student learning in the areas of self-control, self-management, and self-efficacy.

5. *Peer characteristics and conditions.* These are characteristics and interactions with a referred student's peer group that function as either antecedent or consequent stimulus control conditions for specific behaviors. While these peer characteristics may be real or simply perceived by the referred student, they do nonetheless have some impact on a referred situation.

6. *Student characteristics and conditions.* These often are preexisting characteristics and conditions, including neurological, physiological, genetic, and biochemical conditions, that relate primarily to a student's behaviors, emotions, affects, and cognitions. Cognitions here include a student's attitudes, expectation, beliefs, attributions, thoughts, and internal processes. All of the characteristics or conditions in this area should directly link to the social-emotional development of students and their ability to conform to social and situational demands. These characteristics and conditions also involve the behaviors that students exhibit that directly support their academic and social learning and progress such as their motivation, their self-competence skills, and their use of appropriate social skills.

Using the model above, school psychologists can generate hypotheses that explain why specific behaviors or emotional responses are occurring. Their personality assessment then can be guided by these hypotheses, not by some random search for eligibility or pathology. Unfortunately, even when assessing for eligibility or pathology, many school psychologists use a test-by-test approach rather than a strategic approach in which assessment is used to answer specific questions that lead to interventions. School psychologists must make this paradigm shift; otherwise personality assessment will remain a random, subjective, and disconnected process that does not lead to effective or defensible interventions or services.

The best practice cited above create a foundation for sound personality assessment. Below, these approaches are extended and operationalized by focusing on the classification systems, pragmatic beliefs, applied approaches, and fundamental procedures that translate into effective personality assessment. After reading this chapter, school psychologists should have not only an updated perspective as to how to link personality assessment and intervention but also a working model that helps them to implement this important process.

BASIC CONSIDERATIONS

Assuming a psychological and educational perspective of personality assessment, school psychologists must attend to the available classification systems that are used to categorize referred child and adolescent behavior. While a functional analysis of a student's behavior and affect will be more relevant to planning viable and effective intervention programs, the presence of these classification systems cannot be ignored, given their widespread use and their determination of much of our diagnostic nomenclature. Three different classification systems, with their strengths and weaknesses briefly will be reviewed: The IDEA definition of SED, DSM-IV, and empirically based classification approach.

The IDEA Definition

Most states (approximately 75%) use the actual or an adapted IDEA definition of SED, even though they may not use the label seriously emotionally disturbed. Despite the apparent consensus, the fact remains that the IDEA definition (a) is predominantly an educational definition that does not lend itself to psychological differentiation or analysis, (b) requires behavioral operationalization in order to be used in a consistent manner, (c) necessitates only a yes or no diagnostic decision, and (d) encourages a medical model perspective of disturbed behavior. For example, the IDEA definition focuses on conditions that "adversely affect educational performance," desensitizing our schools to children who progress educationally but still need socialization or mental health services. The definition leaves vague phrases — e.g., "inappropriate types of behaviors or feelings," "under normal circumstances," "for a long period of time," and "to a marked degree" — to the state, school district, or individual multidisciplinary team to interpret and operationalize. This creates, at best, a great potential for inconsistency across referred children and, at worst, conditions allowing unchecked bias, inequity, and prejudice. Finally, the definition permits a simplistic "yes, the child qualifies as an SED child" or "no, the child does not qualify" mentality, which suggests that the child owns or does not own the causal pathology. This discourages an ecological perspective that focuses more on functional assessment, intervention, and problem resolution.

Over the past 4 years, the Mental Health and Special Education Coalition, made up of numerous special education, mental health, and parent advocacy associations and groups (including NASP), has crafted a new definition that is a marked improvement, both conceptually and functionally, over the current SED definition. Submitted to Congress (but not yet approved), this proposed definition is written as follows:

> I. The term *emotional or behavioral disorder* means a disability characterized by behavioral or emotional responses in school programs so different from appropriate age, cultural or ethnic norms that they adversely affect educational performance. Educational performance includes academic, social, vocational or personal skills. Such a disability —
>
> A. is more than a temporary expected response to stressful events in the environment;
>
> B. is consistently exhibited in two different settings, at least one of which is school-related; and
>
> C. persists despite individualized interventions within educational settings unless the education agency and the parent(s) agree that the child or youth would not benefit from such interventions.
>
> II. Emotional or behavioral disorders can co-exist with other disabilities.
>
> III. This category may include children or youth with schizophrenic disorders, affective disorders, anxiety disorders or other sustained disorders of conduct or adjustment when they adversely affect educational performance in accordance with Section I. (Forness & Knitzer, 1992)

While further operationalization is needed even with this definition, it clearly addresses many of the cultural, normative, clinical, developmental, situational, and behavioral issues missing from the current SED definition. Further, this proposed definition is more consistent with the multimethod, multisource, multisetting perspective advocated in the field.

While the coalition definition is a great improvement, the school psychologist still must take a leadership role at the district and individual multidisciplinary team levels to operationalize and systematize the SED definition currently in use. This will require discussions with all team members as to (a) what is typical and expected behavior in the classroom and school building from both a developmental perspective and a normative (school or community) perspective; (b) what types of behaviors, affects, and interactions fall under the SED definition, thereby requiring programmatic intervention (regardless of its setting); (c) what curricular, instructional, and mental health support services are available to "wrap around" an SED student so that regular classroom placement can continue; and (d) what behavioral frequencies, intensities, and durations are needed for regular versus special education classroom placement decisions. Only by having clear SED procedures and definitions can a multidisciplinary team make consistent, objective, and functional decisions, simultaneously overcoming the weaknesses of the current IDEA definition. Only by operationalizing at a local level can a multidisciplinary team evaluate referred children; be sensitive to a community's individual strengths, weaknesses, history, and problems; and determine what constitutes SED behavior for a specific community.

DSM-IV

The most recent revision of the *Diagnostic and Statistical Manual of Mental Disorders*, the DSM-IV (APA, 1994), was published in May of 1994. Continuing its attempts to describe disorders as behaviorally as possible, the DSM-IV describes the following disorders of infancy, childhood, and adolescence: Mental Retardation, Learning Disorders, Motor Skill Disorders, Pervasive Developmental Disorders, Attention-Deficit Disorders and Disruptive Behavior, Feeding and Eating Disorders of Infancy or Early Childhood, Tic Disorders, Communication Disorders, Elimination Disorders, and Other Disorders of Infancy, Childhood, or Adolescence. Critically, there are other disorders that extend from infancy, childhood, and/or adolescence through adulthood that are classified elsewhere in the DSM-IV.

The DSM-IV was published after extensive committee work, research reviews, and clinical trials, and it continues the behavioral and functional focus of its predecessor, the DSM-III–R. Significantly, as the DSM-IV is evaluated during the next few years, it will be important to determine whether the concerns previously expressed for the DSM-III–R exist for its newer version. For example, will the DSM-IV be more able to demonstrate its reliability and validity across all its diagnostic areas? Will the adapted psychosocial stressor and adaptive functioning scales (and axes) of the DSM-IV be more functional and socially valid? Will the adaptations especially to the diagnoses listed under Disruptive Behavior and Attention-Deficit Disorders prove any more applicable or useful to the school setting?

As an example of this latter point, the inattention subset of DSM-IV's Attention-Deficit/Hyperactive Disorder (AD/HD) diagnosis is made for a disturbance of at least 6 months duration, beginning no later than age 7, and involving at least six of nine specific manifestations. Critically, the psychologist does not need to specify which six of the nine behaviors exist when the diagnosis is made, and some of these behaviors (e.g., "often has difficulty organizing tasks and activities," "often forgetful in daily activities," "often does not seem to listen to what is being said to him or her") are behaviorally imprecise and dependent at times on situation-specific factors. Thus, one AD/HD diagnosis could be functionally different from another, and there would be no way for a psychologist to determine which of the various AD/HD behaviors were present unless they were specified in a psychological report. Without specifying the behaviors of concern, then, the AD/HD diagnosis is of limited use, especially in the development of appropriate intervention strategies and programs. When the behavioral manifestations are specified, the AD/HD label is basically unnecessary — school psychologists' interventions will address these problematic behaviors, not the so-called diagnostic labels.

In summary, there are few, if any, compelling reasons why school psychologists need to use the DSM system. While some feel that their ability to label a referred problem means that they understand it and are ready to successfully resolve it, this has never been empirically demonstrated. What has been demonstrated is that the identification of behavioral skill deficits, performance deficits, and self-management deficits and their behavioral contexts and contingencies can be successfully addressed, and that these approaches are often more parsimonious, efficient, and well-accepted by referral sources and referred individuals.

Empirically Based Classification Approaches

An empirically based classification system can be developed from the factor analytic results of the many researchers (e.g., Edelbrock & Achenbach, 1980; Quay, 1983) who have analyzed the characteristics of emotionally disturbed and behaviorally disordered children and adolescents. At a broad-band level, two factors — Internalizing or Overcontrolled and Externalizing or Undercontrolled — have consistently been identified. These factors broadly describe children who demonstrate depressed, withdrawing, or uncommunicative behavioral styles versus hyperactive, aggressive, or delinquent behavioral styles, respectively. At a narrow-band level, many different behavioral clusters have been identified, some of which vary developmentally across age, sex, and research sample. To date, the following narrow-band factors have been most consistently identified: Aggressive, Delinquent, Attention Problems, Thought Problems, Social Problems, Anxious/Depressed, Somatic Complaints, and Withdrawn Behavior (Achenbach, 1991), and Conduct Disordered, Socialized Aggression, Attention Problems/Immaturity, Anxiety-Withdrawal, Psychotic Behavior, and Motor Excess (Quay, 1983).

From a psychometric perspective, the factor analytic approach, with its broad-band and narrow-band factors, represents a sophisticated approach to classifying behavior. However, this classification approach does not facilitate accurate identification of all problems or the development of appropriate interventions in every case. In fact, it must be emphasized that (a) the factors derived from this approach are statistical clusters of correlated behaviors or characteristics, (b) there are numerous theoretically and empirically based decisions made by the researcher that influence which items appear on which factors, and (c) the factors ultimately are named by the researcher. By way of implication, this suggests that (a) some factors may be multidimensional in nature despite the fact that a single factor is presented, (b) the presence of an item within a factor does not imply a causal relationship relative to the diagnostic label of the factor, and (c) there is a level of subjectivity involved in finalizing or naming any factor, especially at the narrow-band level.

While the empirically based classification approaches have some limitations, they do provide a functional framework from which to organize a sound, school-based classification system that differentiates among referred students' primary social-emotional problems and that facilitates a link between assessment and intervention. One excellent example of an empirically based classification system that has been adapted into a state special education definition for behaviorally disordered students exists in Iowa. There, a behaviorally disordered student is defined in this way:

> 1. Behaviorally disordered is the inclusive term for patterns of situationally inappropriate behavior which deviate substantially from behavior appropriate to one's age and significantly interfere with the learning process, interpersonal relationships, or personal adjustment of the pupil to such an extent as to constitute a behavioral disorder.
>
> 2. Clusters of behavior characteristics of pupils who are behaviorally disordered include: Cluster I — Significantly deviant disruptive, aggressive or impulsive behaviors; Cluster II — Significantly deviant withdrawn or anxious behaviors; Cluster III — Significantly deviant thought processes manifested with unusual communication or behavioral patterns or both; and Cluster IV — Significantly deviant behavior patterns characterized by deficits in cognition, communication, sensory processing or social participation or a combination thereof that may be referred to as autistic behavior. A pupil's behavior pattern may fall into more than one of the above clusters.
>
> 3. The determination of significantly deviant behavior is the conclusion that the pupil's characteristic behavior is sufficiently distinct from his or her peer group to qualify the pupil as requiring special education programs or services on the basis of a behavioral disorder. The behavior of concern shall be observed in the school setting for school-age pupils. It must be determined that the behavioral disorder is not maintained by primary intellectual, sensory, cultural or health factors.

> 4. In addition to those data required within the comprehensive educational evaluation for each pupil requiring special education, the following areas of data collection shall be gathered when identifying a pupil as behaviorally disordered which describe the qualitative nature, frequency, intensity, and duration of the behavior of concern. If it is determined that any of the areas of data collection are not relevant in assessing the behavior of concern, documentation must be provided explaining the rationale for such a decision. (Wood, Smith, & Grimes, 1985)

This definition emphasizes many of the critical best practices points discussed so far in this chapter. The definition (a) validates referred children's atypical behavior by comparing it to behavior that is developmentally expected at their chronological age levels and to those behaviors normatively observed in their classroom- or community-based peer group; (b) emphasizes students' behavioral, affective, and interpersonal progress from a psychological perspective and their learning and instructional progress from an educational perspective; (c) acknowledges and synthesizes the empirical literature by specifying four major clusters of atypical behavior; and (d) recognizes that behavioral and emotional handicaps can be situation- and setting-specific and that referred behaviors occur within an environmental context that must be incorporated into the intervention program. While this definition is admittedly behavioral in orientation and nature, it is clear that behavioral assessment and intervention approaches are now the national norm (Grosenick, George, & George, 1987). As with any special education SED definition, this definition will need further operationalization by school psychologists within their individual school districts as part of a comprehensive approach to effective service delivery for referred and identified SED students.

Pragmatic Beliefs

As a review and extension of the discussion above, five pragmatic beliefs are essential to a best practices approach to personality assessment (Knoff, 1986). These beliefs, critical both to the conceptualization and operationalization of the assessment process, involve the following.

1. The need for an ecological/environmental orientation to personality assessment suggests that referred students are best understood by investigating the family, school, and community systems in which they have been and are now interacting. In most cases, these systems have determined or influenced referred students' developmental progress, and analyses of the interdependent relationships between these systems and students may explain certain behaviors, affects, and interactions of concern. Clearly, a child's anxious or phobic behavior toward school is best understood when it is known that the child has been corporally punished and embarrassed in full view of her or his peer group for forgetting to bring in her or his homework. Similarly, a child who never attended preschool and has been in four different kindergartens and first grades due to frequent moves may never have learned appropriate play or socialization behavior. The ecological/environmental assessment efficiently helps to explain many referred problems, while decreasing the tendency to assume that the child should be the exclusive focus of the assessment process. This perspective also increases the probability that the ecological/environmental contingencies that explain referred problems will be recognized and directly addressed with appropriate intervention approaches.

2. The need for multimethod, multisource, multisetting assessments suggests that the identification and analysis of referred problems are more accurate when the assessment procedures used involve multiple techniques and approaches from multiple informants who have interacted with the referred student in multiple situations and settings (Gresham, 1983). This process minimizes diagnostic and analytical errors and poorly developed intervention programs that have occurred because (a) only one assessment technique was used (e.g., a projective test) rather than a more comprehensive assessment battery (e.g., behavioral observations plus behavior rating scales plus home and school interviews plus appropriate developmental scales); (b) only one assessment source (e.g., the mother) was used, when multiple sources might have indicated that the mother had excessively high expectations for the child; and because (c) the child was evaluated in only one setting, when a multiple setting evaluation might have indicated that the child experienced a traumatic event in a different setting and generalized the emotional response across settings. While some problems are legitimately related to specific individuals or settings, the multimethod, multisource, multisetting process increases assessment and intervention reliability and validity while assuring attention to the ecological/environmental considerations described above.

3. The need for a developmental context to assessment suggests that school psychologists must be knowledgeable and sensitive to the typical and atypical developmental characteristics that occur for the independent variables of age, sex, multicultural status, and socioeconomic status, and that all personality assessment data must be analyzed and interpreted from this perspective. For example, it makes no sense to interpret projective drawings as psychologically significant when a child has obvious visual-motor deficiencies or when developmental norms indicate that a student cannot form meaningful, interactive figures in such drawings at that age. It is also somewhat dangerous for school psychologists to depend on their

own, or others', subjective interpretations of any assessment method if no sound empirical base exists to guide and support those conclusions. Finally, it is important to consider referred children's cognitive-developmental status when interpreting any personality assessment data gathered directly or indirectly. Clearly a mildly retarded child's social skills and emotional reaction to frustration may be closely related to his or her cognitive skills and developmental status.

In this context, it is important to note that much of the projective drawing literature depends on clinically based, rather than empirically based, studies and case examples (Knoff, 1990). While projective drawings may provide insight into a student's behavioral cognitions and belief systems, their results can only be interpreted as hypotheses that are in need of objective and multimodal validation. In contrast, even though a common set of narrow-band scales have been created, the various Achenbach (1991) behavior rating scales have been factor-analyzed across age and sex, and the problems scales are scored separately by gender and age (ages 4–11 and 12–18).

4. The need for a problem-solving and hypothesis-testing approach to assessment suggests that the personality assessment process should systematically involve a problem identification, problem analysis, intervention, and evaluation sequence so that problems are accurately (and ecologically) identified and then comprehensively analyzed (using multimethod, multisource, and multisetting assessments) before any intervention is attempted. This process explicitly and logically links assessment results with intervention programs, and ensures that these programs are not implemented until an explanation as to why a referred problem or situation is occurring has been found. Within the problem-solving process, then, it is important to behaviorally operationalize referral problems, to generate hypotheses to explain why the problem exists, to empirically confirm (through personality assessment) these hypotheses, and then to develop and implement the interventions that are logically linked to the confirmed hypotheses.

Using this approach, the most critical step in the personality assessment process is the generation of hypotheses. In trying to explain a student's verbal aggression toward her or his teachers, for example, a number of potential hypotheses concerning the cause (student, teacher, classroom/school, peer, curricular, home/community) exist. However, if a diagnostic interview suggested that the referred student verbally lashes out at teachers when confronted with work at too high an academic level (the hypothesis), and this hypothesis was empirically confirmed, then the intervention is obvious: give this student academic material at an academic level where she or he can succeed. At this point, the only questions are whether this intervention can be accommodated in the regular classroom and whether the intervention decreases the frequency, duration, and intensity of the verbal aggression.

In the example above, note that (a) the need for a classification decision is independent of the reasons explaining the referred problem, and dependent only on the intensity of the behavior when compared developmentally and normatively and its resistance to intervention; (b) a placement decision would be needed only if it was determined that the intervention program (i.e., providing material at the student's instructional level) would be more successfully implemented in a special education setting; and (c) there is a definite link between the assessment process and the interventions recommended. To summarize, this problem-solving hypothesis-testing process allows school psychologists to strategically choose which assessment instruments and approaches are needed to confirm the hypotheses generated. In this way, the school psychologist controls the entire process; personality assessment instruments are used to facilitate rather than dictate all interpretations and conclusions.

5. The need for objective and observable assessment strategies emphasizes that all assessment hypotheses must be validated objectively and, ideally, through observable means. While objectivity is clearly relative, school psychologists must use instruments and techniques that have demonstrated their ability to validly and reliably generate the desired data and information. Thus the psychometric properties of all personality assessment instruments must be investigated on an ongoing basis, and only the soundest instruments should be used among those that advertise similar assessment purposes or domains. In context, comprehensive behavioral observation is still the best way to assess the presence of specific social-emotional skills or deficits. Behavioral observation requires a clear operationalization of targeted skills or deficits, and the results include the frequency, intensity, and duration of a referred student's behavior and the antecedent, consequent, and ecological conditions that exist when these behaviors are exhibited. Collecting accurate and useful data through behavioral observation requires training, organization, and practice; it is a learned skill. But when done effectively, behavioral observation becomes the cornerstone of any personality assessment, and the source of the objective data that can confirm or reject many important hypotheses about a referred student.

BEST PRACTICES IN PERSONALITY ASSESSMENT

Rather than describing the various personality assessment approaches, tools, and techniques in a somewhat random, categorical form, this section will discuss the assessment process from the beginning to the end using the Referral Question Consultation (RQC) process (Knoff & Batsche, 1991a). Assumed throughout this entire discussion are the beliefs that (a) school psychologists have the professional training and autonomy to determine what personality assessment procedures are necessary for any SED (or related) referral; (b) school psychologists ultimately identify and implement intervention programs that offer the highest probability of treatment success; and (c) service delivery is provided within the context of consultee acceptability, social validity, treatment integrity, and transfer of training and generalization. While some states and school districts require the completion of certain personality assessment techniques (e.g., projective tests) with any SED referral regardless of the circumstances surrounding the referral, this is not a best practices approach. Personality assessment is an individualized process that should be fully in the hands of the professional school psychologist, and the requirement that certain techniques be used is personally and professionally appalling and potentially unwise or even damaging to the referred student.

RQC Process

The RQC process involves 10 interdependent steps after an individual student has been referred.

1. Review all existing data available on the referred student and collect any additional background data as appropriate.

2. Meet with the referral source in a consultative interview to behaviorally define his or her initial concerns, to identify the need for additional data to finalize the behavioral operationalization of these concerns, to informally test some initial hypotheses, and to determine the referral source's assessment goals and commitment to the RQC process.

3. Develop hypotheses to explain the initial concerns as behaviorally operationalized.

4. Develop prediction statements from the generated hypotheses.

5. Develop data-based referral questions that will guide the assessment process and confirm or reject the generated hypotheses.

6. Select multitrait, multimethod assessment procedures that will specifically answer the referral questions and facilitate the link between assessment and intervention.

7. Apply the assessment and background data so as to answer the referral questions and to confirm or reject the generated hypotheses.

8. Select and implement intervention strategies consistent with those hypotheses that have been confirmed.

9. Monitor change in the area of the initial concern to determine the impact of the intervention.

10. Develop a written report that documents the RQC process, the interventions tried, and the intervention outcomes as they relate to the resolution of the initial referred concerns.

Review of the data. When a school psychologist receives a referral from a teacher, the first step in the RQC process is to review essential information about the referred student and to collect any additional background data that may be important to know before interviewing the teacher. The review of essential information typically centers around an analysis of four possible existing student areas or folders: (a) the student's cumulative folder, (b) the administrative/discipline folder, (c) relevant teachers' academic work sample folders, and (d) the special education/remedial education (e.g., Chapter I) folder. In addition to the information available in already-existing records and student folders, it may be time- and cost-efficient to collect other data from teachers and other sources prior to an initial consultation interview. This information may be collected through behavior checklists, behavior rating scales, ecological or developmental status surveys or questionnaires, or objective personality scales or inventories, and it may, for example, provide the answers to routine developmental (and other) status questions so that precious interview time can focus on the areas most relevant to the referral concerns. Significantly, this information also may facilitate a more accurate and in-depth behavioral operationalization of the teacher's initial concerns, identify possible correlates of those concerns, identify possible student assets and strengths, and generally prepare the school psychologist more thoroughly for the consultation interview and the teacher's (and others') perception of the referral problem.

Behavior rating scales. Behavior rating scales are one of the most efficient, sound, and effective ways (a) to identify a referred student's behavioral strengths and weaknesses, (b) to validate a referral source's initial concerns, (c) to evaluate the severity of a wide range of specific behaviors, (d) to assess for atypical patterns of behaviors or clinical entities, and (e) to complete one facet of a multisource, multisetting evaluation. With literally hundreds of rating scales on the market, school psychologists' ability to choose the rating scales that will best accomplish their assessment goals without sacrificing psychometric quality is critical. To that end, Edelbrock (1983) noted that behavior rating scales differ dramatically across a number of critical dimensions, and he provided the following suggestions to help school psychologists become better consumers of behavior rating scales.

1. School psychologists need to match their RQC and assessment goals to the results that a particular behavior rating actually provides. Some behavior rat-

ing scales (a) assess clinical, home, or school concerns; (b) are descriptive, prescriptive, or diagnostic; (c) evaluate specific behaviors or simply provide a checklist indication that they exist; (d) are unidimensional or multidimensional in scope; (e) rate actual student behaviors or characteristics that correlate with certain behavioral conditions; (f) focus exclusively on behavioral deficits or problems, or assess both behavioral deficits and assets (Wood, Smith, & Grimes, 1985). School psychologists must consider these rating scale characteristics, the referred problem, and the diagnostic and intervention questions to be answered. Clearly, behavior rating scales must be chosen in an informed manner with proper consideration for their purposes and intended uses.

2. School psychologists need to recognize that the technical adequacy of behavior rating scales varies greatly and needs to be analyzed prior to their use. Among the variables to evaluate are (a) how items were selected during the development of the behavior rating scale, (b) what response scaling approach was used (e.g., true/false, often/sometimes/never), (c) how the scale was developed and constructed, (d) the scale's standardization and norming procedures, and (e) the scale's validity and reliability data.

3. School psychologists need to evaluate whether behavior rating scales evaluate global or specific levels of manifested behavior, the time frames within which referred students are evaluated (e.g., every 1, 3, or 6 months), and who the optimal respondent should be. To clarify this point, some behavior rating scales require that the informant be the target child's mother or teacher, others can be completed simply by an individual who genuinely knows the child or who has interacted with the child over a long period of time.

4. Finally, school psychologists must assess how behavior rating scales control for response bias — for example, for halo effects, leniency or severity effects, and central tendency or range restriction effects. Without sufficient controls for bias, a behavior rating scale's results are of extremely limited use.

From an RQC perspective, school psychologists must strategically use all of the potential information generated by a behavior rating scale. School psychologists also must recognize that behavior rating scales measure the perceptions of the scale's respondent and that these perceptions must be validated. Finally, too often school psychologists simply use the broad-band and narrow-band results of a behavior rating scale, concluding and writing in their personality assessment reports, for example, that a referred child "has significantly high externalizing or acting-out tendencies, and that he manifests hyperactive, aggressive, and delinquent behavior" by virtue of elevated scores on those scales. Unfortunately, conclusions like these are simplistic at best and downright inaccurate and damaging at worst. A best practices approach to behavior rating scale interpretation (a) begins at the individual item level to determine what specific behaviors or behavioral correlates are of greatest concern to the scale respondent; (b) continues at the narrow-band scale level, first to determine if the significant items are consistent with the label of the specific scale that contains them, and then to determine if the scale's scores indicate a statistical or clinical problem; and (c) ends at the broad-band scale level where the most global interpretations of a referred student's behavior are considered. Significantly, the data generated in this manner are compared with other information at this first step of the RQC process and then integrated into the consultation interview for further confirmation and analysis.

Objective personality scales. Objective personality assessment scales assess specific diagnostic areas (e.g., self-concept, anxiety, depression) or multidimensional areas of referred children's personality functioning. At this RQC stage, it may be best to use the latter type of objective scale, so that a broad range of psychological problems or concerns can be sampled for later, more in-depth investigation. Currently, a number of multidimensional objective scales are available, including the Personality Inventory for Children and for Youth, the Children's Personality Questionnaire, the Early School and High School Personality Questionnaires, the Minnesota Multiphasic Personality Inventory–Adolescents, and the Millon Adolescent Personality Inventory. The Personality Inventory for Children, for example, has 12 clinical scales — Achievement, Intellectual Screening, Development, Somatic Concerns, Depression, Family Relations, Delinquency, Withdrawal, Anxiety, Psychosis, Hyperactivity, and Social Skills — all of which can stand alone as separate clinical entities.

Like behavior rating scales, the development and psychometric properties of all objective scales must be investigated, and only those scales that have clinical (as opposed to research) validation and utility should be used. Also, like the behavior rating scales, analyses of individual items on these instruments — as opposed to unconditional acceptance of scale and profile results — are more likely to facilitate the development of effective interview questions and hypotheses for later validation through the RQC process.

The consultative interview. The consultation interview, involving those individuals referring and relevant to a specific child, is the most important activity in the RQC process. While the long-term impact of the consultation interview focuses on intervention planning and implementation, the interview has the following goals as the second step of the RQC process:

1. To engage the teacher (and/or parents) in the comprehensive problem-solving process, so that they are committed to the entire process and to the service delivery directions that result from the process.

2. To obtain additional relevant information beyond that already collected during the review of data step and to integrate and apply all of the data to the next steps of the RQC process.

3. Using all the data collected, to clarify the initial concerns of the referral source resulting in a behavioral definition and operationalization of the behavior(s) of concern.

4. To determine what interventions have already been attempted and to evaluate the treatment integrity and impact of those interventions.

5. To begin to generate tentative hypotheses that explain the clarified concern and to outline the remainder of the RQC assessment process for the consultee.

Armed with the teacher- and parent-completed referral and background information forms, behavior rating scales, and objective rating scales, the school psychologist can begin the diagnostic interview process at a much higher level of sophistication than when starting the process with a simple statement of concern. In fact, with the social, behavioral, developmental, educational, and familial history of the student already documented by both teachers and parents, a great many background questions are unnecessary, and the school psychologist need only pursue those questions that are directly or indirectly related to the referral problem. Thus the school psychologist now can listen to teachers' and parents' descriptions of the referral problem, match them to the behavior and objective rating scale data that has already been completed, behaviorally define and operationalize the stated problems and the behavioral ecology where they exist, and begin to generate hypotheses that explain the referred behavior or situation.

Development of hypotheses. After completing the needed consultation interviews and collecting the necessary relevant information, the RQC process proceeds to the development of hypotheses that explain the now-clarified and behaviorally operationalized referral concerns. At this point in the process, the school psychologist and others have a great deal of information about the referred behavior, the settings within which this behavior occurs, and other significant ecological environments and contexts that are related to the referred student and the referral situation. Now it is time to integrate all of this information and generate hypotheses that answer the question "Why is this referral situation happening?" These hypotheses are generated using the variables and conditions in Table 1, and they conform to the principle that hypotheses must be relevant, predictive, and measurable.

Development of predictions. The next step in the RQC process is the development of predictions. Predictions are statements, developed from specific hypotheses, that identify what should or should not happen if a hypothesis is true or untrue, respectively. For example, if we hypothesize "A child aggresses because his peers verbally taunt him," then our prediction statements would be "When peers verbally taunt the child, then the child will aggress against the peers," and "When peers do not verbally taunt the child, then the child will not aggress against the peers."

Prediction statements are set up to evaluate the hypothesis and its converse. That is, it is necessary to demonstrate that the referral concern exists when our explanatory hypothesis is true, and it is also necessary to demonstrate that the concern does not exist in the absence of our hypothesis. For example, given the example above we need to demonstrate that the child aggresses only when his peers verbally taunt him. If he aggresses when the peers ignore him, then our hypothesis is not true in that the verbal taunting is not consistently related to an aggressive response.

Another important point about predictions is that they must be evaluated without changing the student's natural environment whenever possible. That is, predictions should be tested, as much as possible, without implementing new interventions and thus without changing the referral setting. If a student, for example, is referred because she is out of her seat a great deal of the time, and your hypothesis is that she gets out of her seat during unstructured times in the classroom, then your prediction statements would be "When unstructured time occurs in the classroom, then the student will get out of her seat" and "When structured time occurs in the classroom, then the student will stay in her seat." In order to evaluate these prediction statements in a naturally occurring way, we would need to observe during times when the teacher routinely allows the classroom to be structured and unstructured. If we asked the teacher to artificially plan special structured and unstructured times, this would constitute an intervention that changes the normally occurring classroom routine. When such changes occur, in the absence of baseline data and a multiple baseline or reversal research design, we cannot truly be sure whether the referred student's behavior is a function of the classroom structure (or lack of structure) or the change in the classroom routine.

Development of referral questions. Referral questions are data-based questions, derived from the prediction statements, that quantitatively confirm or reject the original hypotheses related to a referral concern. More specifically, referral questions are typically yes or no questions, or questions related to fre-

quency, duration, latency, or intensity. Referral questions are important for a number of reasons. First, referral questions actually drive the assessment and decision-making process. While assessment procedures must be reliable, valid, and psychometrically sound, the form and format of the referral questions actually determine what assessment methodologies must be used. Second, referral questions provide an internal check for the RQC process to ensure that the parents' or teachers' referral concerns still are being addressed. Third, referral questions help to organize the report-writing process. In fact, reports documenting the confirmation of hypotheses, the development of interventions, and the successful results of those interventions can be structured in a question-and-answer format around the referral questions. Thus reports should do more than describe the referred student; they should answer questions that lead to and relate to interventions.

To be effective and appropriate, referral questions must have the following characteristics:

1. Referral questions must be clearly defined, they must be directly related to the previous prediction statements, and they must require data that are observable and measurable.

2. Referral questions must be agreed upon by the referral source and other evaluation team members,

and they must lead to or have the potential to lead to interventions, not labels.

3. Referral questions should result in clear, definitive answers. Ideally, referral questions should be answered in a yes-or-no or other data-based format, and they should be able to directly confirm or reject hypotheses generated to explain the referred problem.

For the scenario above with an aggressive child, the referral questions should be:

1. Do peers verbally taunt the child? (yes or no?)
2. Is the child aggressive with peers? (yes or no?)
3. Do peers ignore or leave the child alone? (yes or no?)
4. Is the child aggressive with peers? (yes or no?)

To confirm the hypothesis in this situation, questions 1, 2, and 3 would have to be answered yes and question 4 would have to be answered no.

Assessment. Once referral questions are developed, assessment begins. It is important to note that only those assessment instruments and processes needed to answer the referral questions are necessary. This discourages the random use of personality assessment tools in a search for pathology, and it makes the RQC process both efficient and effective. In this context, most RQC referral questions will be answered jointly by the school psychologist and the classroom teacher, and they will most likely involve direct assessment in the setting where the referred student's behavior or problem is occurring. These assessments involve low-inference procedures (e.g., the use of behavioral observation), use multitrait, multimethod assessment procedures, and directly link assessment and intervention.

Briefly, there are four behavioral observation approaches commonly noted in the literature: naturalistic free behavior, naturalistic role-play, analog free behavior, and analog role-play observations (Cone, 1978; Keller, 1986). Naturalistic observation involves observing referred students in the actual settings where their behaviors of concern or the conditions that most influence those behaviors are exhibited. When used to confirm hypotheses generated to explain well-identified behaviors, naturalistic observations are both time- or cost-efficient. In addition, they are the most ecologically sound of the behavioral approaches, and they are the least inferential relative to interpretation within the personality assessment context. Analog observation involves observing referred students in controlled situations that simulate particular environments or circumstances of behavioral concern. These situations are used to objectively evaluate a priori hypotheses that explain referred behaviors or situations and to provide detailed and comprehensive functional analyses of significant facets of a referred student's behavior. Significantly, analog observations attempt to maximize the ecological accuracy of simulated situations so that interpretation requires as little inference as possible. They are also very time-efficient, given their intent to elicit behaviors that test the referral-related hypotheses.

Free behavior observations occur when referred students are allowed to freely react and interact within environments that are either unmanipulated and naturalistic or simulated and analog. No artificial rules or constraints are placed on the students, and they respond to situations in any way that they choose. Role-play observations occur as referred students are requested to follow preconceived and semistructured scripts that focus on interactions or situations relevant to particular hypotheses. These observations involve more inference than free behavior observations, because the students' role-played behavior is assumed to represent behavior that would be exhibited if the situation actually occurred in a real-life situation. Once again, role-play observations can occur in both naturalistic or classroom-based settings and analog or simulated settings; naturalistic observations are assumed to require less interpretive inference than analog observations.

While behavioral observations may appear to be the easiest and most objective of all personality assessment approaches, they actually involve very complex processes. In addition to choosing which observational approach to use, school psychologists must decide which recording method to use (e.g., narrative, interval, event, ratings), and how to best assess the antecedent conditions, environmental characteristics and interactions, overt and covert contingencies, planned and unplanned consequent conditions, and unintended effects of a referred behavior within its unique ecology. While behavioral observation is one of the most effective ways to validate hypotheses generated during the problem identification phase of the personality assessment process, it also can be misused or abused. School psychologists must recognize that it is a learned skill that requires training, practice, and more practice.

Once data are collected, the referral questions can be answered and the original hypotheses can be confirmed or rejected. At this point, the multidisciplinary team can take the confirmed hypotheses, begin to develop intervention plans, and outline a formative report organized around the hypotheses tested, the referral questions generated, and the data collected.

Other assessment techniques. Beyond behavioral observation, there are a number of other personality techniques that can be used during the assessment process to answer specific RQC questions. These include objective personality assessment techniques that focus on single diagnostic dimensions when needed — e.g., self-concept, anxiety, depression — and family assessment techniques (Knoff, 1986). Projective instruments, to a large degree, cannot validate a priori hypotheses; they only generate additional hypotheses that need subsequent validation and thus are useful only (if at all) in the earliest stages of the RQC process. The reader is strongly encouraged to read Knoff's (1990; 1993) research review and analyses of projective drawing approaches. The primary conclusions from these reviews are that projective instruments do not have sufficient empirical validation for clinical use, they are both time- and cost-inefficient, and their use necessitates additional assessments to validate their assertions.

A Brief RQC Case Study

To quickly illustrate the RQC process in action, let's consider a fourth-grade boy (Jason), who has been referred by his regular classroom teacher because of a number of incidents in which he becomes verbally angry, pushes his desk violently away from himself and toward other students, and refuses to calm down and follow teacher directions. Typically, we would behaviorally operationalize this problem in more specific detail by completing a series of consultative interviews, making some classroom observations, and perhaps having the teacher complete a behavior rating scale or two. But, for the purposes of this example, let's just generate one hypothesis for each of the six hypothesis areas delineated in Table 1 that potentially explain this behavior. Putting these hypotheses in the recommended format, we would say that Jason becomes verbally angry, pushes his desk violently away from himself and toward other students, and refuses to calm down and follow teacher directions because:

- *Family-oriented hypothesis:* He sees his father respond similarly to his mother when she asks him to do something around the house.
- *Classroom-oriented hypothesis:* There is so much noise in the classroom that he can't attend to and complete his work.
- *Teacher-oriented hypothesis:* The teacher constantly orders him around, giving him five negative comments for every one positive comment.
- *Curriculum-oriented hypothesis:* His mathematics text and assignments are above his instructional level.
- *Peer-oriented hypothesis:* His peers reinforce him with attention and laughter each time he does this.
- *Student-oriented hypothesis:* He forgets to use the "stop and think" steps of his prosocial skills/problem-solving self-management intervention.

At this point, we would generate prediction statements and referral questions for each of these hypotheses, and then proceed to collect the data to confirm or reject each hypothesis. Continuing our example for just one of the hypotheses above, the curriculum-oriented hypothesis, we would predict that when Jason's mathematics assignments are above his instructional level, then he will become verbally angry, push his desk violently away from himself and toward other students, and refuse to calm down and follow teacher directions. Conversely, when Jason's mathematics assignments are at his instructional level, then he will not become verbally angry, not push his desk violently away from himself and toward other students, and not refuse to calm down and follow teacher directions.

The data-based referral questions needed to assess this hypothesis, drawn from the prediction statements, are these: "Are Jason's mathematics assignments above his instructional level?" and "Does Jason become verbally angry, push his desk violently away from himself and toward other students, and refuse to calm down and follow teacher directions?"

At this point, the school psychologist or the teacher can collect the data to answer these questions through (a) an assessment of the instructional level of Jason's math assignments over time, and (b) observations of Jason's behavior during math. If the data demonstrate that Jason acts out when math assignments are above his instructional level, but does not act out, is calm, and appropriately follows teacher directions when math assignments are at his instructional level, then the hypothesis has been confirmed. If the data do not support one or both of these situations, then the hypothesis should be rejected. For the confirmed hypothesis, the intervention program would focus on (a) ensuring that current math assignments are at Jason's instructional level, (b) working with Jason to increase his mathematics skill levels so that his instructional level progresses, and (c) teaching Jason coping skills so that he is able to more adaptively handle the academic and personal frustration that occurs when he receives a mathematics assignment above his instructional level. If the hypothesis is rejected, then another hypothesis must be generated, assessed, and validated — intervention programs cannot be developed without one or more confirmed hypotheses.

SUMMARY

Once the referral problem has been comprehensively identified and analyzed from ecological, developmental, and environmental perspectives using a hypothesis-testing, problem-solving process in which hypotheses are evaluated using objective, multimethod, multisource, multisetting methods, the school psychologist is ready to develop an intervention program. Intervention should be clearly linked to the assessment process, the referral concerns identified and confirmed by the personality and behavioral assessments, and the factors that interact and influence the referral concerns. As noted earlier, intervention is useless unless viable, acceptable, and socially valid approaches are successfully implemented with ongoing attention to treatment integrity and treatment evaluation. In the end, the success of the personality assessment process will be evaluated most clearly through the behavioral and treatment changes resulting from the intervention program.

To summarize, personality assessment is a process, not a product. It is simply not enough to understand a child's behavioral or social-emotional problems. School psychologists must move from problem analysis to interventions that resolve these problems and facilitate children's normal development and positive mental health. This chapter has been devoted to this ultimate best practice. Hopefully, we will soon see the day when school psychologists provide comprehensive services, when intervention success is valued over special education placement, and when social, emotional, and behavioral success is an explicit educational goal and emphasis.

ANNOTATED BIBLIOGRAPHY

Knoff, H. M., & Batsche, G. M. (1991b). *The Referral Question Consultation process: Addressing system, school, and classroom academic and behavioral problems.* Tampa, FL: Authors.

An introductory manual to the Referral Question Consultation process, which utilizes a systematic problem-solving process to address referred problems. Using consultation processes as a foundation, this process ensures a direct link between case-related assessment and intervention by generating hypotheses that explain the referred behavior, confirming behavioral predictions based on these hypotheses, and developing interventions that address these behavioral explanations. This manual describes this decision-making process and relates it to use by support teams, team reports, and triennial reevaluations. It also provides a step-by-step teaching of the RQC process complete with numerous case examples and practice exercises to facilitate reader mastery.

Knoff, H. M. (Ed.). (1986). *The assessment of child and adolescent personality.* New York: Guilford.

A comprehensive volume on personality assessment specifically with children and adolescents written in four parts. Part 1 discusses the theoretical bases underlying the personality assessment process; Part 2 describes the development, administration, scoring, and interpretation of the predominant techniques now used in personality assessment from behavioral to projective to family assessment; Part 3 describes how to communicate and translate personality assessment results into effective intervention strategies; and Part 4 summarizes the issues currently in the field and presents future directions and needs. A single-authored update of this book is currently in preparation and should be available in 1996 or 1997.

Knoff, H. M. (1990). Evaluation of projective drawings. In C. R. Reynolds & R. W. Kamphaus (Eds.), *Handbook of psychological and educational assessment of children: Vol. 2. Personality, behavior, and context* (pp. 89–146). New York: Guilford.

BEST COPY AVAILABLE

A critical chapter in an important edited volume devoted to personality assessment and sound clinical and school practice. The chapter reviews all of the current research on projective drawings and concludes that much of the "evidence" is provided through case studies or research containing serious methodological flaws. Projective drawings are put into a problem-solving context that suggests limiting their use while increasing their accountability – for those who still want to use them. While the debate on projectives rages on, this chapter provides an objective and empirical perspective in the midst of the storm.

Martin, R. P. (1988). *Assessment of personality and behavior problems: Infancy through adolescence.* New York: Guilford.

An important book that approaches perso/*Assessment of personality and behavior problems: Infancy through adolescence.*/nality assessment from a developmental and integrative perspective. It is divided into four sections, which discuss issues and assumptions implicit in the personality assessment process, techniques and decisions underlying the design of assessment instruments, and actual instruments and procedures used from infancy through adolescence. The book reviews specific personality assessment tools, presents case study examples, and addresses the advantages and disadvantages of different assessment and interpretation approaches.

Sattler, J. M. (1990). *Assessment of children.* San Diego, CA: Author.

The third edition of Sattler's comprehensive volume covering all facets of the assessment process with children and adolescents has some critical chapters related to personality assessment: assessment of adaptive behavior and behavior problems; assessment of behavior by interview methods; assessment of behavior by observational methods; assessment of ethnic minority children; and others related to consultation, conferencing, and report writing. Sattler balances theory, empirical research, and pragmatic best practices approaches in a way that facilitates appropriate assessment processes and a clear assessment to intervention linkage.

Best Practices in Multidimensional Assessment of Emotional or Behavioral Disorders

Stephanie H. McConaughy
University of Vermont

David R. Ritter
Burlington (Vermont) School District

OVERVIEW

When the district school psychologist read the referral for evaluation, it was clear that the student's classroom behavior warranted concern. The student was not completing assignments and was disruptive in class. Teachers also reported episodes of defiance and refusal to comply with requests and school rules. The student was often sent out of class as a disciplinary procedure and as a result, missed instruction and was falling behind in academic performance. On the playground, the student frequently fought with others, though it was not always clear who initiated the fights. Such behavior was understandably disturbing to others. Whether the same problems constituted an emotional or behavioral disorder was another question.

The school psychologist recalled that children are often labeled emotionally or behaviorally disordered because their behavior is bothersome to teachers (Algozzine, 1977). (The term "children" includes adolescents.) Indeed, teachers have applied the terms "behavior disorder" to as many as 22% and "emotional handicap" to 16% of children in regular classes (Tisdale & Fowler, 1983). Certain types of problems appear to be especially disturbing to teachers, such as noncompliant, defiant, or oppositional behaviors (Coleman & Gilliam, 1983; Mattison, Morales, & Bauer, 1992). More passive behaviors, such as withdrawal or anxiousness, appear to be less disturbing to teachers, probably because they do not interfere as much with classroom activity (Coleman & Gilliam, 1983).

In formulating an assessment plan, the school psychologist considered three different perspectives on emotional or behavioral disorders. One perspective views *child psychopathology* as the basis for disorder. This viewpoint seeks to identify emotions and behaviors exhibited by the child that are symptoms or characteristics of different patterns of psychopathology. It also acknowledges that familial and environmental factors may contribute to the development of child psychopathology. Examples are mental illness in a parent, parental alcohol or drug abuse, low socioeconomic status, life stress, and divorce (Jensen, Bloedau, & Davis, 1990; Jensen et al., 1990; Stanger, McConaughy, & Achenbach, 1992).

A second perspective focuses on *behavioral-environmental interactions* as the basis for disorder. Instead of identifying symptoms or characteristics of psychopathology in the child, this perspective emphasizes reciprocal interactions between the child's behavior and the environment (Bandura, 1986). Behavioral excesses or deficits are then thought to constitute emotional or behavioral disorders. This viewpoint considers family factors as well but from a different angle, such as incompatibility between parents' and children's interactional styles, parents' maladaptive reactions to the needs or problems of children, and parents' attributions about intentionality, consequences, and circumstances surrounding behavior (Grotevant, McRoy, & Jenkins, 1988). Aspects of the school environment and interactions with teachers are also important considerations within this perspective (Ysseldyke, Christenson, & Thurlow, 1987).

Yet a third perspective emphaszes the effectiveness of *interventions* for emotional or behavioral problems, directly linking assessment of "disorders" to prior individual educational programming (Mowder, 1980). This viewpoint defines emotional or behavioral disorders by the extent to which the child's behavior proves to be resistant to interventions (Gresham, 1991).

In our case example, the school psychologist recognized that the three perspectives were not mutually exclusive. Each perspective needed to be considered in evaluating the referred student's problems and determining the extent to which such problems constituted an "emotional or behavioral disorder" (EBD). The school psychologist also recognized that the primary goals for assessments of EBD should be to identify students' needs and to assist in developing and implementing interventions, when they are warranted (National Association of School Psychologists, 1993). To accomplish these general goals, school-based assessments of EBD can serve several different purposes:

1. Help teachers better cope with behavior problems in regular education classrooms.

2. Help students improve their behavior and school performance.

3. Determine a student's eligibility for special education services.

4. Refer children (and perhaps families) for mental health services outside of the school setting.

Depending on the purposes of assessment, the school psychologist may emphasize each of the three perspectives on EBD to different degrees. To help teachers cope with classroom behavior, the behavioral-environmental interaction or intervention-focused views of EBD are likely to offer the most effective strategies. In such cases, the school psychologist could employ behavioral consultation methods (see Kratochwill, this volume) to determine specific excesses or deficits in the student's behavior. Specific antecedents and consequences of the problem behaviors would also be identified. In consultation with teachers, the school psychologist could then evaluate the effectiveness of prior interventions and the feasibility of alternative interventions in the regular education setting. The behavioral-environmental interaction or intervention-focused views of EBD are also likely to be effective for working directly with students to improve their behavior and school performance. In such cases, the school psychologist may provide individual or group counseling to a student as well as consult with teachers. For these purposes, it is usually not necessary to label or classify a student's problems into categories that represent different patterns of psychopathology.

In contrast, to determine eligibility for special education services, federal and state laws require classifying children's problems according to categories of psychopathology or "disabilities." Providing mental health services outside of school may also require some form of classification of psychopathology, for example, in order to obtain third party insurance payments. Making appropriate classifications requires assessing the severity of problems and different patterns of behavior, as well as considering behavioral-environmental interactions and the effectiveness of prior interventions. Basic considerations regarding the classification process are discussed in the next section. A subsequent section describes "best practice" procedures for assessing and classifying emotional or behavioral disorders in order to determine special education eligibility.

BASIC CONSIDERATIONS

Two different approaches have been taken toward classifying children's emotional or behavioral disorders: categorical systems and quantitative taxonomies (Achenbach, 1993; McConaughy & Skiba, 1993). Categorical systems classify problems in a *dichotomous* present-versus-absent fashion. In a categorical system, specific criteria are listed to describe features of a disorder. If all of the required features are met, an individual is judged to have the disorder; if all of the required features are not met, the individual is judged not to have the disorder.

In quantitative taxonomies, individuals are scored according to the *degree* to which they manifest a given feature or behavior. Rather than judging features as present or absent, features are scored on quantitatively graded scales that represent frequency, duration, and/or intensity. In empirically based taxonomies, statistical procedures, such as principal components or factor analysis, are employed to derive syndromes or groupings of problems that tend to co-occur. Scores for the groupings of features are then summed to produce an overall score for each syndrome. Standard scores can also be used to indicate how an individual scores on a syndrome relative to normative reference groups.

Quantitative taxonomies and categorical classification systems are not incompatible. Scores on quantitative scales can be dichotomized to define normal versus clinical ranges. However, because it is not assumed that each syndrome represents a distinct or separate disorder, profiles of high and low scores are also possible across a set of syndromes. Thus, quantitative taxonomies can provide a more differentiated method than categorical systems for assessing the severity and patterning of children's problems.

The DSM-III-R and DSM-IV

The American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders* (DSM-III-R; 1987; DSM IV, 1994) is one of the most widely used categorical systems for classifying adult and childhood psychopathology. The DSM-III-R and DSM-IV list specific features describing over 40 numerically coded disorders of childhood and adolescence, as well as several adult disorders applicable to children. In each case, defining features of disorders are judged to be present or absent. Children judged to meet the requisite number of features (or symptoms) are diagnosed as having a DSM disorder. Common childhood diagnoses include conduct disorder, oppositional defiant disorder, attention deficit hyperactivity disorder, and separation anxiety disorder (which can include school phobia). Examples of adult diagnoses that can be applied to children include major depression, dysthymia (a chronic form of sad affect), schizophrenia, obsessive compulsive disorder, anxiety disorder, and phobias.

The utility of the DSM for determining special education eligibility has been questioned (Gresham & Gansle, 1992; Sinclair & Forness, 1988). There is general agreement that DSM diagnoses are *not* required by federal law for assessing emotional or behavioral disorders or determining eligibility for special education services. However, DSM diagnoses may be useful for communicating with mental health professionals providing services outside of the school setting, and they are sometimes required for mental health administrative purposes.

Empirically Based Taxonomies

The profiles scored from the *Child Behavior Checklist* (CBCL; Achenbach, 1991b) and its related forms are examples of a quantitative taxonomy (Achenbach, 1991a, 1993). The CBCL is designed to obtain parents' ratings of emotional or behavioral problems of children aged 4 to 18. Parents rate their child on each of 118 items according to a 3-point scale. The *Teacher's Report Form* (TRF; Achenbach, 1991c), covering ages 5 to 18, and the *Youth Self-Report* (YSR; Achenbach, 1991d), covering ages 11 to 18, are designed to obtain teachers' ratings and adolescents' self-ratings of problems. The CBCL and YSR profiles also provide scores for social competencies, while the TRF profile provides scores for academic performance and school adaptive functioning.

To provide a quantitative taxonomy, the 1991 CBCL, TRF and YSR scoring profiles each contain eight empirically based cross-informant syndrome scales: Withdrawn, Somatic Complaints, Anxious/Depressed, Social Problems, Thought Problems, Attention Problems, Delinquent Behavior, and Aggressive Behavior. The profiles also provide scores for higher order groupings of Internalizing and Externalizing problems, as well as total problems. In this taxonomic system, the names of the syndrome scales describe the problems they represent and are not considered to be "diagnostic" labels. (For details of the derivation of syndromes, see Achenbach, 1991a, 1993, and McConaughy, 1993a). Cutpoints for defining normal, borderline, and clinical range scores on the problem scales can be used for judging the deviance of a child's reported problems relative to nationally representative normative samples.

Several other rating scales also contain empirically based syndromes for assessing children's emotional or behavioral problems. For example, the *Behavior Assessment System for Children* (BASC; Reynolds & Kamphaus, 1992) is scored on 10 clinical syndromes: Aggression, Anxiety, Attention Problems, Atypicality, Conduct Problems, Depression, Hyperactivity, Learning Problems (teacher form only), Somatization, and Withdrawal. The BASC also contains four scales assessing positive traits: Adaptability, Leadership, Social Skills, and Study Skills (teacher form only). The *Revised Behavior Problem Checklist* (RBPC; Quay & Peterson, 1987) is scored on six syndromes: Anxiety-Withdrawal, Attention Problems-Immaturity, Motor Tension-Excess, Psychotic Behavior, Socialized Aggression, and Conduct Disorder. The *Walker Problem Behavior Identification Checklist* (WPBIC; Walker, 1983) is scored on five syndromes: Acting Out, Distractibility, Disturbed Peer Relations, Immaturity, and Withdrawal. Other rating scales, such as the *Behavior Evaluation Scale–2* (BES–2; McCarney & Leigh, 1990), may provide quantitative scores for problems, but they do not contain empirically based syndrome scales derived through statistical procedures.

Special Education Classification

The Individuals with Disabilities Education Act (IDEA, 1990; formerly the Education of the Handicapped Act, EHA) represents another form of categorical classification. The IDEA defines 10 types of disability that entitle children to special education services. Although general criteria are described for each disability area, a categorical decision must be made regarding the presence or absence of a given disability.

Children with emotional or behavioral disorders are most likely to qualify for special education under the IDEA category of serious emotional disturbance (SED), originally defined in the EHA as follows:

> (i) The term means a condition exhibiting one or more of the following characteristics over a long period of time and to a marked degree, which adversely affects educational performance:
>
> A. An inability to learn which cannot be explained by intellectual, sensory, or other health factors;
>
> B. An inability to build or maintain satisfactory interpersonal relationships with peers and teachers;
>
> C. Inappropriate types of behavior or feelings under normal circumstances;
>
> D. A general pervasive mood of unhappiness or depression;
>
> E. A tendency to develop physical symptoms or fears associated with personal or school problems.
>
> (ii) The term includes children who are schizophrenic. The term does not include children who are socially maladjusted unless it is determined that they have a serious emotional disturbance (20 U.S.C. § 1401 [a] [1]; 34 C.F.R. § 300.7 [g])

To meet the criteria for SED according to the above definition, a child must exhibit *one or more* of the five characteristics A through E *or* have a diagnosis of schizophrenia. In addition, *all three* qualifying conditions listed in paragraph (i) must apply to at least one of the identified characteristics. That is, the characteristic(s) must exist over *a long period of time, to a marked degree*, and must *adversely affect educational performance*. A child exhibiting at least one of the five characteristics or schizophrenia, and meeting all three qualifying conditions, is judged to have SED. A child who does not meet criteria for SED is judged to be ineligible for special education on the basis of an emotional or behavioral disorder.

Professionals and advocacy groups have criticized the IDEA definition of SED as being overly restrictive and not supported by legal precedent or educational and clinical research (Forness, 1992; Forness & Knitzer, 1992; Skiba & Grizzle, 1992). Accordingly, a National Mental Health and Special Education Coalition has proposed the following new definition of "emotional or behavioral disorder" (EBD) as a substitute for the current IDEA definition of SED:

> (1) The term "emotional or behavioral disorder" means a disability that is characterized by behavioral or emotional responses in school programs so different from appropriate age, cultural, or ethnic norms that the responses adversely affect educational performance, including academic, social, vocational or personal skills; more than a temporary, expected response to stressful events in the environment; consistently exhibited in two different settings, at least one of which is school-related; and unresponsive to direct intervention applied in general education, or the condition of a child is such that general education interventions would be insufficient.
>
> The term includes a disability that co-exists with other disabilities.
>
> The term includes a schizophrenic disorder, affective disorder, anxiety disorder, or other sustained disorder of conduct or adjustment, affecting a child if the disorder affects educational performance as described in paragraph (1) (*Federal Register*, 1993, Vol. 58, No. 26, p. 7938).

The National Association of School Psychologists has endorsed the proposed definition of EBD (National Association of School Psychologists, 1993). After receiving public comments, Congress must decide whether to substitute the proposed definition of EBD for the current definition of SED in its reauthorization of the IDEA. The next section describes "best practice" procedures for special education assessments that are applicable to both definitions. While the focus is primarily on special education evaluations, most of the procedures described can also be utilized for the other assessment purposes discussed earlier.

BEST PRACTICES FOR ASSESSMENT OF SED/EBD

A multidisciplinary team is required for all special education evaluations. Because of their special expertise regarding emotional and behavioral problems, school psychologists should serve as members of multidisciplinary teams in all school-based assessments of SED/EBD. (Other evaluations such as special educators, classroom teachers, and speech/language pathologists, are also likely to assess additional areas of concern.) In practice, school psychologists may become involved with children exhibiting behavioral or emotional problems long before they are referred for special education evaluations. For example, a school psychologist may have already consulted with teachers to develop classroom interventions or provided counseling to such children (or their families). The school psychologist's role in assessment of SED/EBD may involve any or all of the following:

- Reviewing referral and screening information.
- Planning assessment and/or interventions.
- Conducting screening or assessment procedures.
- Interpreting assessment data.
- Linking assessment data to intervention planning, implementation, and evaluation. (National Association of School Psychologists, 1993.)

Professional ethics require that all evaluators be familiar with relevant instruments and procedures and select only those they are trained to administer and interpret with confidence. However, not all measures produce quantifiable data or meet psychometric standards for reliability and validity. Thus, evaluators must be aware of the advantages and limitations of various procedures and report their findings accordingly. No single measure or procedure should be considered definitive in providing evidence of SED/EBD. Instead, determination of SED/EBD must be based on an integration of findings from a multidimensional approach to assessment, as discussed in the following sections.

Multidimensional Assessment

Educational and mental health professionals concur that multidimensional assessment is necessary to obtain a full view of children's emotional and behavioral functioning (Achenbach, 1991a; Gresham, 1985; Marsh & Terdal, 1988; McConaughy, 1993b, 1993c). Multidimensional assessment has the additional advantage of not limiting data gathering to only one source or one informant. "Best practice" for assessing SED/EBD dictates some combination of the following procedures: standardized behavioral rating scales; standardized self-reports; interviews with parents, teachers, and the child; direct observation of the child; and reviews of relevant background information. Personality assessment may also be included to assess social and emotional functioning, as described by Knoff (this volume). As the first step in multidimensional assessment, data should be gathered from three major sources, as outlined in Table 1: parent reports, teacher reports, and direct assessment of the child. Instruments and procedures are discussed below for each data source listed in Table 1.

Standardized Behavioral Rating Scales

Standardized behavioral rating scales provide efficient methods for obtaining parent and teacher reports of children's emotional and behavioral problems. Numerous rating scales have been developed for this purpose. Some instruments are "omnibus" measures that assess a wide range of potential problems. Examples are the CBCL, TRF, BASC, RBPC, and WPBIC described earlier. Other instruments are more narrow in their focus, such as the Conners (1990) scales for assessing attention deficits and hyperactivity. Instruments of choice for assessment of SED/EBD are those with empirically based problem scales, large normative samples covering a wide age range for both sexes, and demonstrated reliability and validity. Standardized behavioral rating scales meeting these criteria have the following advantages:

1. Information is quantifiable and thus amenable to psychometric standards of reliability and validity.

2. Information is organized in a systematic way by aggregating problems according to different scores and scales.

3. Empirically based syndromes cluster problems that co-occur in large samples of referred children, rather than being based on assumed diagnostic categories.

4. Normative data provide a standard for judging the severity of problems by comparing an individual to large samples of nonreferred children.

5. Multiple items on omnibus measures provide data on a broad range of potential problems, rather than limiting the focus only to referral concerns or behaviors in one area.

6. Rating scales are economical and efficient because most can be completed by the relevant information in 10 to 15 minutes and can be scored quickly by hand or computer.

7. Sets of related rating scales can be used to compare similar data from multiple informants, such as parents, teachers, children's self-reports, and observers.

When choosing a standardized behavioral rating scale, it is important that it meet acceptable psychometric standards of reliability and validity. It is equally important that the scale provide useful information for assessing SED/EBD and planning appropriate interventions. To accomplish these goals, the following criteria should be considered:

1. Do the items on the rating scale pertain directly to the child's observable behavior rather than consequences of behavior (e.g., often in trouble), inferences about behavior (e.g., lacks social skills), or family situations (e.g., on welfare)?

2. How are the items scaled? Simple yes/no scaling is less effective than multiple point scales, since most behaviors vary in degree. In general, 3- or 4-point scales have shown better discriminatory power than dichotomous scales (e.g., yes/no or true/false) or scales where 0 equals "never."

3. Are the items on the scale appropriate for the particular situation? For example, some behavior is more likely to be observed by teachers (e.g., can't follow directions), while other behavior is better observed by parents (e.g., has nightmares).

4. Are there procedures or forms for comparing information from multiple raters who observe the child under different conditions in and outside of school?

While standardized behavioral rating scales provide quantifiable data on children's problems, they also have the following limitations:

1. Rating scale results do not identify the etiology or causes of children's problems. Most rating scales assess current functioning over a limited time frame, such as 2 or 6 months. To identify factors that may precipitate and sustain identified problems, evaluators must obtain additional information on factors, such as biological conditions, earlier development, social interactions, and environmental circumstances.

2. Rating scale results do not dictate choices for interventions. While results are useful for identifying specific areas of concern, additional data are necessary to determine appropriate and feasible interventions in each case.

3. Rating scales are not "objective" measures of children's problems. Like most other assessment procedures, rating scales involve people's perceptions of problems. Perceptions can vary from one rater to the next and can be influenced by the rater's memory, values, attitudes, and motivations, as well as situational factors.

Research has shown that similar informants in similar settings are more likely to agree on ratings of children's problems than are informants in different situations (Achenbach, McConaughy, & Howell, 1987). For this reason, it is important to obtain ratings from multiple informants so that variations in perceptions can be compared and integrated with other findings. As "best practice," it is recommended that an omnibus standardized behavioral rating scale be completed by at least one parent and a teacher who knows the child well. If a child has multiple teachers,

it is useful to obtain ratings from several teachers to compare problems across different school environments. Rating scale results must then be integrated with results from other procedures discussed in the following sections.

Standardized Self-Reports

Standardized self-reports are valuable for obtaining older children's perceptions of their own competencies and problems. Respondents are usually asked to rate their feelings or behaviors on dichotomous or multistep scales. The *Youth Self-Report* (YSR; Achenbach, 1991d) is an example of a standardized omnibus self-report for children aged 11 to 18. Examples of standardized self-reports for more targeted problems include the *Child Depression Inventory* (CDI; Kovacs, 1992), the *Reynolds Adolescent Depression Scale* (RADS; Reynolds, 1987), and the *Piers-Harris Children's Self-Concept Scale* (Piers, 1984).

Scores on standardized self-reports can be compared with reports from other informants, such as parents and teachers. To facilitate cross-informant comparisons, the 1991 YSR profile has the same eight empirically based syndromes as the CBCL and TRF, plus Internalizing, Externalizing, and total problem scales. When interpreting results from self-reports, evaluators should consider how responses might be affected by a child's reading ability, insight, motivation, and willingness to disclose sensitive personal information.

Interviews

In both clinical and school settings, interviews are frequently used to assess children's emotional and behavioral problems (Gresham & Davis, 1988; Hughes & Baker, 1990; McConaughy, in press). As "best practice," parent, teacher, and child interviews are all recommended for assessment of SED/EBD. If standardized behavioral rating scales and self-reports are obtained, as recommended, interviews can be tailored to gather information that may prove less accessible by these other procedures.

The first and second columns of Table 1 list general areas to be covered in parent and teacher interviews. Each interview begins with questions regarding details of a child's presenting problems. Behavioral interviewing techniques are usually applicable for this process (e.g., see Batsche, this volume; Kratochwill, this volume). Behavioral interviewing elicits information on behaviors to be targeted for interventions. Once specific behaviors have been identified, interviewers should ask about antecedent, sequential, and consequent conditions that precipitate and sustain the behaviors. Interviewers should also inquire about parents' and teachers' feelings toward targeted problems, their usual responses to the problems, and their expectations and preferences for children's behaviors. While the focus of parent and teacher interviews is primarily on children's current behavior, historical information about identified problems should be obtained as well. It is also important to explore other possible problem areas. This can be accomplished by discussing scores and profile patterns obtained from standardized behavioral rating scales, assuming these instruments were completed by parents and teachers in advance of the interviews.

Parents should also be asked about family factors and stressors that may be related to their children's problems. Examples are:

1. Has there been any change in family structure or relationships, such as divorce or a death in the family?

2. Has the child experienced significant or upsetting changes in school?

3. Has there been a significant change in residence or the economic status of the family?

4. Have any members of the family had psychological or psychiatric problems or received mental health services?

5. Has the child experienced significant losses, such as death of a loved one, break-up of peer or romantic relationships, or loss of a pet?

6. Has the child or members of the family experienced any medical traumas, hospitalizations, or serious illnesses?

7. Is there any evidence of alcohol or drug use/abuse by the child or members of the family?

8. Has the child experienced any traumatic episodes, such as a suicide attempt, sexual or physical abuse, violence, or serious accident?

9. Has the child or members of the family ever had trouble with the law or been involved in the juvenile justice system or social service agencies?

To assess the feasibility of different interventions, it is also useful to ask parents and teachers about their typical strategies for coping with identified problems, such as discipline and reward procedures.

The third column in Table 1 lists general areas to be covered in child interviews. Several methods for interviewing children have been developed, including structured interviews, semistructured interviews, and unstructured or nondirective play interviews (Hughes & Baker, 1990; McConaughy, in press). For assessment of SED/EBD, unstructured interviews are the least useful, because it is difficult to quantify their results and clinicians vary widely in their interpretations of children's responses. As a result, unstructured interviews are less amenable to psychometric tests of reliability and validity than are semistructured or structured interviews.

Several structured child (and parent) interviews have been developed for epidemiologic studies and clinical uses. Highly structured interviews require strict adherence to standard procedures for asking questions, rating responses, and ordering items. An example is the NIMH *Diagnostic Interview Schedule for Children* (DISC–2.3; Shaffer, 1992). Less structured interviews also utilize standard question formats but allow the interviewer to adjust the length and order of items to create a more conversational approach. Examples are the *Child Assessment Schedule* (CAS; Hodges, et al., 1982) and the *Schedule for Affective Disorders and Schizophrenia for School-Age Children* (K-SADS; Puig-Antich & Chambers, 1978). The DISC, CAS, and K-SADS, however, have limited utility for special education evaluations of SED/EBD, because they are designed primarily for obtaining DSM diagnoses (for reviews, see Hodges, 1993; McConaughy, in press; McConaughy & Achenbach, 1994).

A well designed semistructured child interview, on the other hand, can provide important information for assessments of SED/EBD (Hughes, 1989; McConaughy, in press). The child interview should be conducted by the school psychologist, or another professional with appropriate clinical training and experience interviewing children. Such interviews offer unique opportunities for evaluating children's coping strategies and their perceptions of significant persons and events related to their problems. They can also provide opportunities for directly observing children's behavior, especially behavior that may impinge on different treatment options. Hughes (1989) cited several important behaviors to note during child interviews, such as response to limit setting, impulsivity, distractibility, reaction to frustration or praise, language skills, responsiveness to the interviewer, emotional reactions, nervous mannerisms and range of affect. The child's behavior and responses during the interview can then be compared to reports from other informants, such as parents and teachers. Finally, a well conducted child interview can serve as the initial step for establishing the rapport necessary for treatment. In this respect, the child interview can serve as a bridge between assessment and intervention.

The *Semistructured Clinical Interview for Children and Adolescents* (SCICA; McConaughy & Achenbach, 1994) is an example of an interview designed for children aged 6 to 18. The SCICA utilizes a semistructured protocol covering different content areas but also has structured rating scales for scoring observed behavior and children's self-reports. The SCICA scoring profile contains eight empirically based syndrome scales, plus Internalizing, Externalizing, and total problem scales for ages 6 to 12. Separate syndromes were derived for scoring observed behavior and self-reports. Profiles for adolescents are being developed. Data obtained from the SCICA can be compared with parent ratings on the CBCL, teacher ratings on the TRF, and self-ratings on the YSR by older children.

Besides providing relevant assessment information, child interviews can be used to assess the feasibility of different school-based interventions and to determine whether referral for mental health or social services outside of school is warranted. For certain purposes, special interviewing techniques or protocols may be indicated, such as assessment of danger to self or others or possible physical or sexual abuse.

Direct Observations

Direct observations are strongly recommended for assessment of SED/EBD. For some children with emotional or behavior problems, direct observations may have already been performed by the school psychologist as part of behavioral consultation with teachers. After a child has been referred for a special education evaluation, additional direct observations should be conducted. These can be done once again by the school psychologist or by other members of the school staff trained in observational techniques. Observations should occur in relevant settings where problems are occurring. It may also be useful to observe the student in other less problematic situations for comparison. Because children's behavior is apt to vary from day to day, it is important to obtain more than one observation. It may be more appropriate to make several observations of short duration (e.g., 10-minute samples on different days), rather than a single lengthy observation. Observing one or two randomly selected "control" children in the same setting affords a comparison with peers in the same environment. Finally, the validity of direct observations may become suspect if children are aware of being observed. This problem can be reduced by using an observer who is not known by the child or who is a regular visitor to the classroom. If the observer is also one of the evaluators, then it is advisable to conduct observations prior to assessing the child.

Direct observations require an independent observer who can record overt behaviors and environmental conditions surrounding the behaviors (see Shapiro, this volume). For optimal effectiveness, direct observations should focus on target behaviors amenable to change. Antecedent and consequent events should also be noted. Observations may utilize narrative recording or empirical methods.

To obtain narrative recordings, an observer writes a description of events that occurred within a given time frame. Methods for narrative recording include descriptive time sampling, antecedent-behavior-consequent (A-B-C) analysis, or daily logs. Narrative recordings are then used to operationally define behaviors that can be targeted for intervention.

Empirical methods require operationally defined behaviors that can be recorded or rated by an independent observer. Once operational definitions have been established, several different techniques can be employed. Continuous recording methods count the number of times that a behavior (or event) occurs within a given period or record the duration of time in which the behavior (or event) was observed. Continuous recording is most effective when behaviors have discreet beginnings and ends, have low to moderate rates of occurrence, and are present only briefly. Time sampling records the presence or absence of operationally defined behavior within short specified time intervals. Time sampling is useful when multiple simultaneous target behaviors hinder continuous recording or when samples of behavior are observed across several different settings.

The *Direct Observation Form* (DOF; Achenbach, 1986) is an example of a standardized rating scale for obtaining time samples. The DOF contains 96 items scored over 10-minute intervals. The DOF scoring profile contains six empirically based syndromes, plus Internalizing, Externalizing, and total problem scales. Children's on-task behavior is also rated at 1-minute intervals over each 10-minute sample. Examples of other procedures and formats for obtaining direct observations are discussed by Batsche (this volume); Rhode, Jenson, and Reavis (1982); and Shapiro (this volume).

Personality Assessment

In some instances, personality assessment can provide additional information on broader aspects of social-emotional functioning. Personality assessment is described in detail by Knoff (this volume). It should be noted, however, that while scoring procedures exist for many personality measures, the interpretation of their results still relies heavily on clinical judgment. Moreover, normative data, reliability, and validity are limited for certain types of procedures, such as projective techniques. Personality assessment, therefore, should be conducted only by psychologists specifically trained in this methodology. Even then, results should be interpreted with caution. Because different examiners often disagree in their interpretations of personality measures, such procedures should *not* be used as primary data sources for assessment of SED/EBD.

Social Skills and Social Reasoning

Assessing children's social skills and social reasoning can be an important dimension in assessment of SED/EBD. Methods most frequently used include behavior observations, rating scales, students' self-reports, and sociometric techniques (see Gresham, this volume). A number of standardized rating scales have been specifically developed to measure social skills. Examples are the *School Social Behavior Scales* (Merrell, 1993), *Social Skills Rating System* (Gresham & Elliott, 1990), and the *Walker-McConnell Scale of Social Competence and School Adjustment* (Walker & McConnell, 1988).

Observations of children's behavior with peers and adults in natural settings, such as the regular classroom or at recess, can also provide information about social skills and relationships. Observing children's behavior during social skills intervention programs or role-playing situations provides a more direct method for assessing specific areas of social reasoning, such as empathy or problem solving, and specific social behaviors, such as giving and receiving praise or criticism.

Co-occurring Conditions

Children with emotional or behavioral problems may also exhibit other problems. Thus, SED/EBD can be an overlapping or *co-occurring* condition with other disabilities. Children who have attention deficit disorders or learning disabilities, for example, frequently display emotional and/or behavioral problems (Barkley, 1990; McConaughy, 1986; McConaughy & Ritter, 1986; Ritter, 1989). Several chronic or acute medical conditions, such as allergies, seizure disorders, traumatic brain injury, and Tourette's syndrome, may have related behavioral characteristics that might prompt referral for evaluation of SED/EBD. Children with intellectual or communication impairments may also exhibit behavior problems. In certain cases, children with other identified disabilities may also be determined to have SED/EBD, if they meet necessary IDEA criteria. However, behavior that is clearly a function of another medical, learning, cognitive, or communication disorder does not necessarily constitute an additional behavioral or emotional disorder.

Achievement and Educational Performance

As with all other special education evaluations, assessment of SED/EBD must include assessment of the child's current academic achievement and educational performance. This information is necessary to determine if identified behavioral or emotional problems adversely affect educational performance, which is one of the qualifying conditions for special education eligibility. Evidence regarding academic achievement can be obtained from standardized tests, curriculum-based assessment, grade reports, and work samples. Evaluation of broader educational performance can focus on school adaptive functioning and academic behaviors, such as productivity. Standardized teacher rating scales, such as the BASC and TRF, provide ratings of academic performance and school adaptive functioning, as well as behavior problems.

Social Maladjustment

Paragraph (ii) of the current IDEA definition of SED specifically excludes "children who are socially maladjusted unless it is determined that they are seriously emotionally disturbed." Certain authors have argued that children with externalizing problems, such as DSM diagnoses of oppositional defiant disorder and conduct disorder, are socially maladjusted, and therefore should be excluded from special education (Slenkovich, 1992a, 1992b). Others disagree, arguing there is no theoretical or empirical basis to exclude youth with externalizing problems from special education (Forness, 1992; Skiba & Grizzle, 1991, 1992).

Research based on quantitative taxonomies, as well as categorical classification systems, has demonstrated high co-occurrence or "comorbidity" between externalizing and internalizing problems (McConaughy, Mattison, & Peterson, 1994; McConaughy & Skiba, 1993). Based on the current IDEA definition of SED, children with comorbid externalizing and internalizing problems should qualify for special education, even if they are considered to be socially maladjusted, if they also meet the SED criteria. As a general guideline, once SED criteria are met, further evidence of social maladjustment is irrelevant for purposes of determining eligibility for special education. The presence of social maladjustment along with SED, however, is an important factor to consider in planning interventions, because children with such problems often require mental health and/or social services in addition to special education to meet their needs (Duchnowski, Johnson, Hall, Kutash, & Friedman, 1993).

Written Psychological Reports

After data gathering has been completed, the school psychologist must integrate relevant findings into a written psychological report. The report should provide specific information that addresses the characteristics and qualifying conditions of the IDEA definition of SED or proposed definition of EBD, if it is adopted. It is not sufficient to merely state that a child has "SED/EBD." The report should provide clear and specific descriptions of the child's emotional or behavioral problems, as reported by parents and teachers and directly assessed through clinical interviews, observations, self-reports, and other measures. Scores on standardized behavioral rating scales and standardized self-reports, in particular, can provide quantitative evidence of the extent to which a child exhibits characteristics of SED/EBD. Accordingly, Table 2 outlines relations between the IDEA criteria for SED and empirically based syndromes scored from the CBCL, TRF, & YSR, BASC, RBPC, and WPBIC. For each instrument, Table 2 lists the syndromes containing problem items that are most closely related to each characteristic of SED. (McConaughy, 1993b, describes applications of CBCL, TRF, and YSR results to the IDEA criteria for SED.)

The written psychological report should also provide information on the duration of identified problems and severity of problems compared to norms for peers of the same age and sex. Standard scores and clinical cutpoints can be examined to determine the degree to which a child's identified problems deviate from problems reported for large normative reference samples. It is also important to indicate how the identified problems may adversely affect academic achievement and other aspects of educational performance. In most cases, additional evidence regarding learning and academic performance will be provided by other evaluators.

Finally, as "best practice," the psychological report should contain specific recommendations that link assessment results to interventions. Examples include recommendations for consultation with teachers, home-school collaboration, behavioral contracts

TABLE 2
Relations between IDEA Criteria for SED and Empirically Based Sundromes

IDEA Criteria for SED	CBCL, TRF, & YSR	BASC	RBPC	WPBIC
Inability to learn	Attention Problems	Attention Problems	Attention Problems-Immaturity	Distractibility
Inability to build or maintain relationships	Social Problems Withdrawn	Withdrawal	Anxiety-Withdrawal	Withdrawal Disturbed Peer Relations

with students, classroom accommodations, schedule alterations, adaptations in teaching strategies, social skills training, and individual or group counseling. The psychological report may also contain recommendations for monitoring the student's behavioral and academic progress, evaluating outcomes of chosen interventions, and making adjustments in interventions as needed to ensure their efficacy and validity. The school psychologist may be directly or indirectly involved in several of the recommended activities.

Need for Special Education Services

If a child exhibits a specific disability, such as SED/EBD, this in itself is not sufficient to qualify him or her for special education services. *Need* for special education must also be documented. That is, the multidisciplinary team must demonstrate that the child needs interventions that cannot be accomplished through remedial education or supplemental services. For many children with behavioral or emotional problems, an array of educational and behavioral interventions may have been undertaken prior to referral for a special education evaluation. If prereferral interventions have produced minimal positive effects on the child's behavior or school performance, then such resistance to change would be evidence of the need for special education services. School psychologists who have been involved in prereferral and regular education interventions can play a key role in multidisciplinary team decisions regarding need for special education and other more intensive interventions.

SUMMARY

"Best practice" procedures were presented for assessing children's emotional or behavioral disorders. A multidimensional approach was recommended, which requires coordinating and integrating information from multiple informants and data sources. Multidimensional assessment assumes that no single method or informant can capture all relevant aspects of children's emotional or behavioral problems. While school-based assessments of emotional or behavioral disorders can serve several purposes, a major emphasis in this chapter was on determining special education eligibility.

Procedures were described for obtaining parent reports, teacher reports, and direct assessment of the child. As "best practice," some combination of the following procedures was recommended: standardized behavioral rating scales; standardized self-reports; parent, teacher, and child interviews; direct observations of the child; and reviews of relevant background information. Some cases may require additional assessment of intellectual ability and communication skills, social skills, and broader aspects of personality. All special education evaluations require assessing the impact of an identified disability on academic achievement and educational performance.

After all necessary data have been gathered, the school psychologist must integrate information in a written psychological report. The report should present specific findings that address the eligibility criteria for serious emotional disturbance (SED), as currently defined in the IDEA, or Emotional or Behavioral Disorders (EBD), if a new proposed definition is adopted. Scores on empirically based syndromes of standardized behavioral rating scales and self-reports can provide quantitative evidence of the characteristics of SED/EBD. Parent, teacher, and child interviews, as well as direct observations, can also contribute evidence of SED/EBD. Normative comparisons on standardized behavioral rating scales and standardized self-reports can determine whether identified problems deviate from expected behavior "to a marked degree." Duration of problems and their adverse effect on educational performance must be documented. The psychological report should also contain specific recommendations that tie assessment results to interventions.

Although major emphasis was placed on assessment of SED/EBD for special education services, many of the evaluation procedures and problem-solving strategies described as "best practice" can also be applied in regular education settings. The recent emphasis on regular education initiatives and total inclusion models call for expansion of the school psychologist's role beyond assessment for special education (e.g., see Batsche, this volume; Graden, this volume). Consultation between school psychologists and classroom teachers can facilitate inclusion of children with emotional or behavioral disorders within regular education settings. Involving school psychologists more directly in regular education interventions should also reduce the need for more restrictive special education placements for many children with emotional or behavioral disorders.

Once interventions have been implemented, it is important to monitor student progress and evaluate outcomes in a rigorous and meaningful fashion. For children with emotional or behavioral disorders, standardized behavioral rating scales and standardized self-reports can be used to obtain baseline data and follow-up assessments of identified problems. Comparison of Time 1 and Time 2 scores on similar measures can determine whether there has been any change in identified problems. To determine whether changes are associated with specific interventions, it is also necessary to make comparisons with other comparable samples of children who have not received the interventions. Monitoring student progress and evaluating outcomes are essential steps for ascertaining which interventions are most effective for which types of problems.
